**Zonal Flow Amplification in Rotating Tokamak Plasmas** Sumin Yi, Jae-Min Kwon, S.S. Kim, and Hogun Jhang Korean Institute of Fusion Energy yism@kfe.re.kr

## ABSTRACT

• Gyrokinetic ITG turbulence simulations show that an equilibrium parallel rotation shear

 $U'_{\parallel,eq}$  amplifies the zonal flow and lowers the turbulence level in the saturated state.

• A potential vorticity (PV) transport analysis elucidates the physics mechanism behind this observation.

• With  $U'_{\parallel,eq}$ , a larger PV flux with a coherent radial structure is driven at the onset time of a zonal flow. The PV convection by the zonal flow induces a PV flux whose radial structure is aligned with the initial coherent zonal flow structure, promoting a positive feedback between the zonal flow and turbulence.

• Without  $U'_{\parallel,eq}$ , the radial profile of the zonal-flow induced flux is inconsistent with that of the zonal flow at the zonal flow onset time, hindering the positive feedback.

# OUTCOME

Turbulence saturation levels for different  $U'_{\parallel 0}$ 

In spite of the continuous increase in the linear instability with  $U'_{\parallel 0}$ , the turbulence levels decrease with a strong  $U'_{\parallel 0} \ge 1.2$ .

**ID: 726** 

## BACKGROUND

- Many tokamak experiments have demonstrated improved core confinement with high toroidal rotation shear  $U'_{\parallel,eq}$  [M. W. Shafer et al 2009, P. Mantica et al 2009].
- A conventional approach based on the competition between two conflicting effects of  $U'_{\parallel,eq}$ : It can destabilize linear instabilities [J. Q. Dong and W. Horton 1993] and/or enhance the E × B shear stabilization [K.H. Burrell et al 1997]. However, this conventional picture is insufficient to explain the impact of the rotation on transport.
- Turbulence-driven zonal flows (ZFs) are a plausible physics mechanism. A gyrokinetic simulation study manifests an essential role of the parallel compression in ZF generation [S. Yi et al 2019]. Because parallel velocity fluctuation and thus its parallel compression are expected to increase with  $U'_{\parallel,eq}$ , zonal flow generation in rotating plasmas can impact on their confinement.

# METHODS

### **Gyrokinetic simulations of toroidal ITG turbulence**

- A global δf particle-in-cell code, the gKPSP code [J.-M. Kwon et al 2012, 2017]
- Adiabatic electron response

Linear growth rate as a function of  $k_{\theta}\rho_i$  (left) and time histories of the potential fluctuation amplitudes (right) for different  $U'_{||0}$  with  $R_0/L_{T0} = 5.2$ .

### Efficient zonal flow generation with $U'_{\parallel 0}$

•With  $U'_{\parallel 0}$ , an initially driven short-radial scale ZF keep its radial structure constant during the whole build-up phase. The ZF is efficiently amplified during a short time interval. The strong ZF shear leads turbulence growth to be quenched at the lower saturation level. •Without  $U'_{\parallel 0}$ , a ZF with a broad radial profile is initially driven. The ZF radial profile

changes in time during its build-up time. The development of the ZF is a long time after its onset. This allows turbulence to reach to a higher level.

#### Enhanced positive feedback between turbulence and zonal flow

- •In the presence of  $U'_{\parallel 0}$ ,
  - $\checkmark$  the enhanced imbalance among  $\Gamma_X$  drives much larger  $\Gamma_\Omega$ .
  - $\checkmark$  The ZF is routed back to the  $\delta N$  evolution and produces a finite PV flux at the ZF onset time.
  - $\checkmark$  The aligned radial structures of the ZF-induced flux  $\Gamma_{\langle\delta\phi\rangle}$  and  $\Gamma_{\Omega}$  persists during the whole ZF build-up phase, and a positive feedback between  $\Gamma_{\langle \delta \Phi \rangle}$  and  $\Gamma_{\Omega}$  effectively works.
  - $\checkmark$  As a consequence,  $\Gamma_{\Omega}$  and thus ZF significantly increase.
- •In the absent of  $U'_{\parallel 0}$ ,
  - $\checkmark$  the radial structure of  $\Gamma_{\langle \delta \phi \rangle}$  is inconsistent with that of  $\Gamma_{\Omega}$  at the ZF onset time.
  - $\checkmark$  The phase difference between the radial structures of  $\Gamma_{\langle\delta\varphi\rangle}$  and  $\Gamma_{\Omega}$  hinders the

- Scans of  $U'_{\parallel 0} \equiv -(a/v_{T0})dU_{\parallel,eq}(r_c)/dr$  with  $R_0/L_{T_0}=5.2$
- Except for the equilibrium sheared rotation and the  $T_{i,eq}$  gradient, other plasma parameters are very similar to the CYCLONE base case.

equilibrium profiles of ion temperature gradient (broken) and parallel rotation (solid)

#### Analysis of potential vorticity (PV) transport

ZF generation can be described by the flux of PV:

$$\frac{\partial V_{\rm ZF}}{\partial t} = \langle \frac{\omega_{ci0}}{n_{i,eq}} \int d\boldsymbol{\nu} \delta F_i \left( c \frac{\hat{\varphi} \times \nabla_{\perp} J_0 \delta \phi}{B_0} \right)_r \rangle \equiv \Gamma_{\Omega} P_i \langle \sigma F_i \left( c \frac{\hat{\varphi} \times \nabla_{\perp} J_0 \delta \phi}{B_0} \right)_r \rangle$$

In terms of the fluid moments of  $\delta F_{i}$ ,

$$\Gamma_{\Omega} \approx \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \delta \phi \right)_r \frac{\delta N}{n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle + \omega_{ci0} \left\langle \left( \frac{c}{B_0} \hat{\varphi} \times \nabla_{\perp} \frac{\nabla_{\perp}^2 \delta \phi}{\omega_{ci}^2} \right)_r \frac{\delta P_{\perp}}{2m_i n_{i,eq}} \right\rangle$$

The gyro-center density  $\delta N$  acts as an effective PV. Then, the contributions of the  $\delta N$  evolution mechanisms on the net PV flux  $\Gamma_{\rm X}$  can be evaluated as follows:

$$\Gamma_{\Omega} = \Gamma_{\parallel} + \Gamma_{B} + \Gamma_{E \times B} + \Gamma_{\langle \delta \phi \rangle} + \Gamma_{NL} + \Gamma_{FLR},$$

$$\Gamma_{X} \equiv \omega_{ci0} \left\langle \left( \frac{c}{B_{0}} \hat{\varphi} \times \nabla_{\perp} \delta \phi \right)_{r} \frac{\delta N_{X}}{n_{i,eq}} \right\rangle,$$

$$\left( -\frac{\partial \delta N}{2} \right\rangle$$

initiation of their positive feedback.

 $\checkmark$  At the saturation time, however, the phases of the radial structures of  $\Gamma_{\langle \delta \phi \rangle}$  and  $\Gamma_{\Omega}$ are synchronized in the inner region. Thus,  $\Gamma_{\Omega}$  can significantly increase.

Radial profiles of zonal flows with  $U'_{||0} = 0.0$  and  $U'_{||0} = 1.6$  at the zonal flow onset time  $t_{ZF0}(a)$  and turbulence saturation time  $t_{SAT}(b)$ .

Here the all  $\partial \delta N / \partial t |_X$  are evaluated term by term.

### CONCLUSION

• A PV transport analysis uncovers that the positive feedback between turbulence and ZF is enhanced with  $U'_{\parallel 0}$  and results in the decreased turbulence saturation level, observed in gyrokinetic simulations. • The self-organization processes in static plasmas show a more complicated behavior. This requires further simulation and theory studies.
