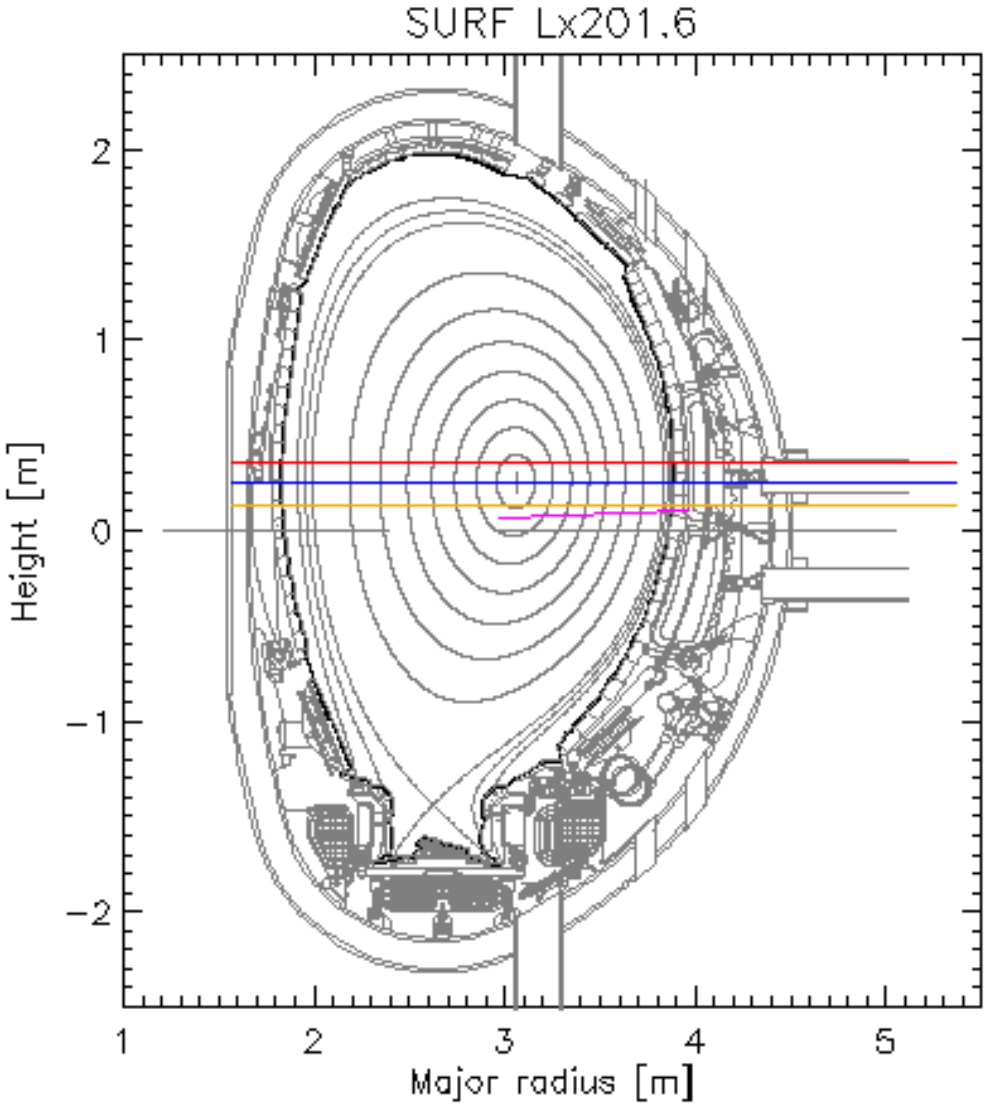
ECE interferometers at JET

JET ECE interferometers

[*S. Schmuck, RSI, 2016*]

- Absolutely calibrated T_e profiles covering [2.5 3.9] m
- Time resolution ~60 Hz (~16 ms/profile)
- X-mode and O-mode polarizations on two LOS.
- Used for ECE radiometer calibration



ECE interferometer X-mode

ECE radiometer

ECE interferometer O-mode

High resolution Thomson scattering

ECE interferometers at JET

JET ECE interferometers

[*S. Schmuck, RSI, 2016*]

- Absolutely calibrated T_e profiles covering [2.5 3.9] m
- Time resolution ~60 Hz (~16 ms/profile)
- X-mode and O-mode polarizations on two LOS.
- Used for ECE radiometer calibration

Data now available in real time

- Approx: $\boldsymbol{B_{approx} = B_{tor}}$

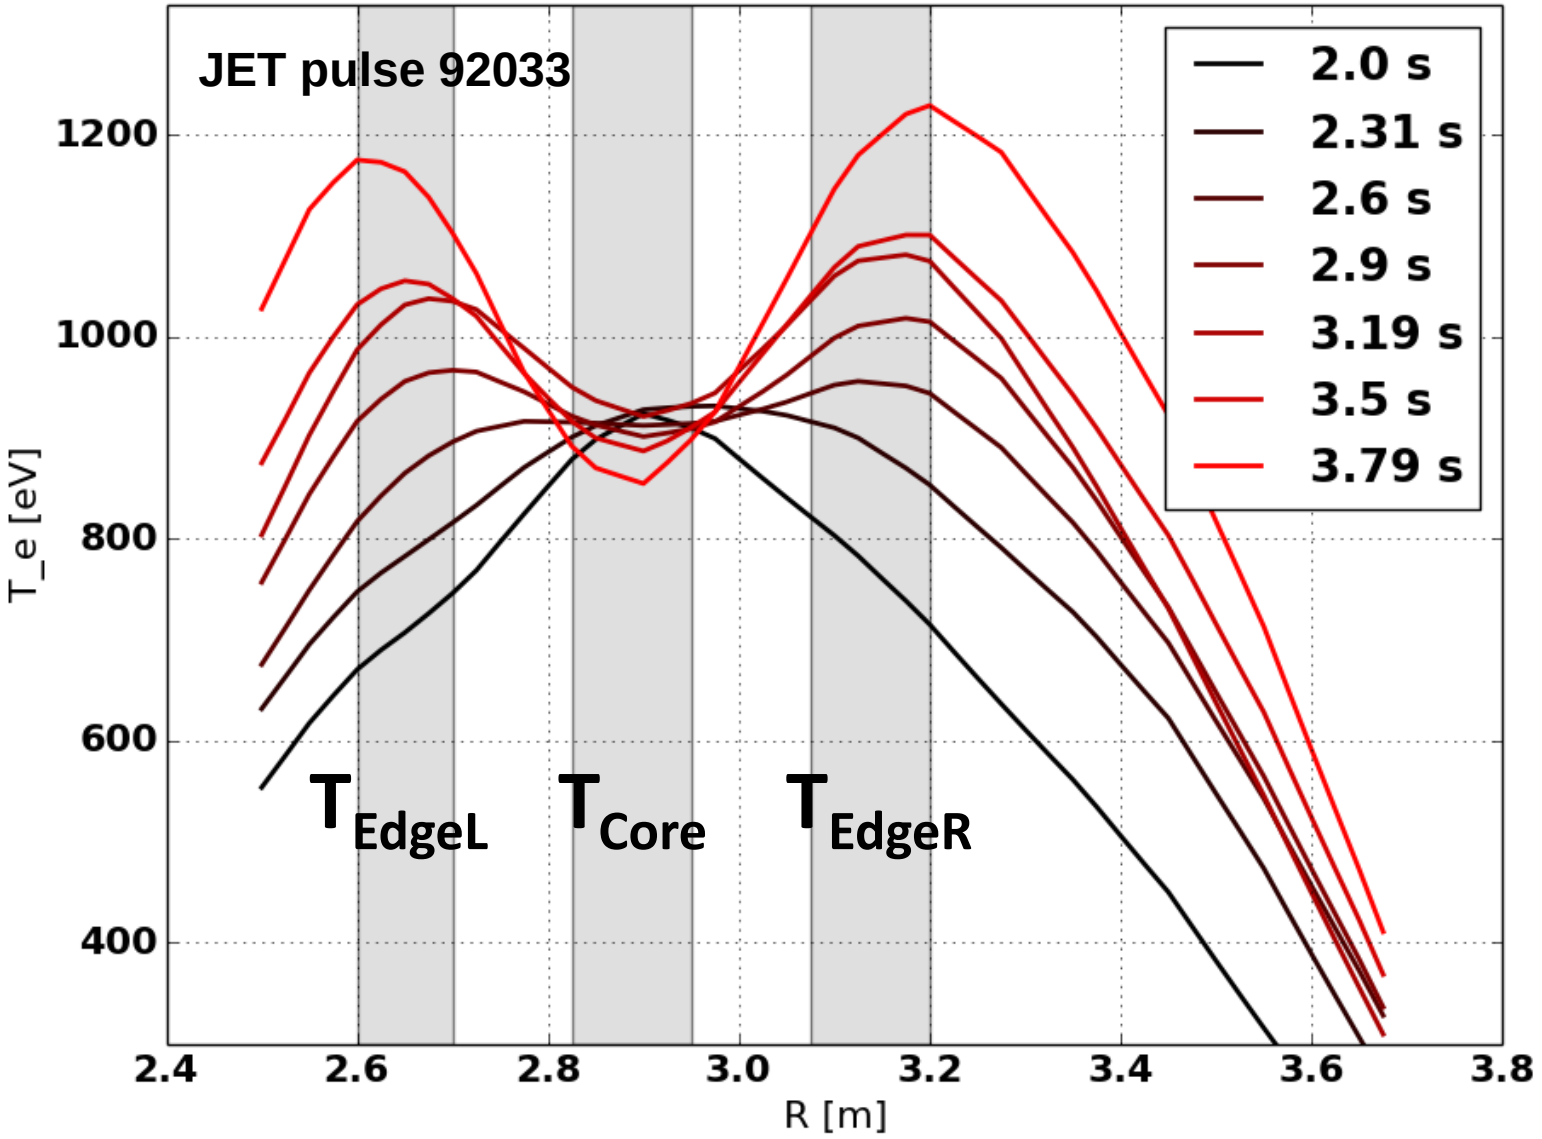
Monitor T_e peaking: a simple, robust metric



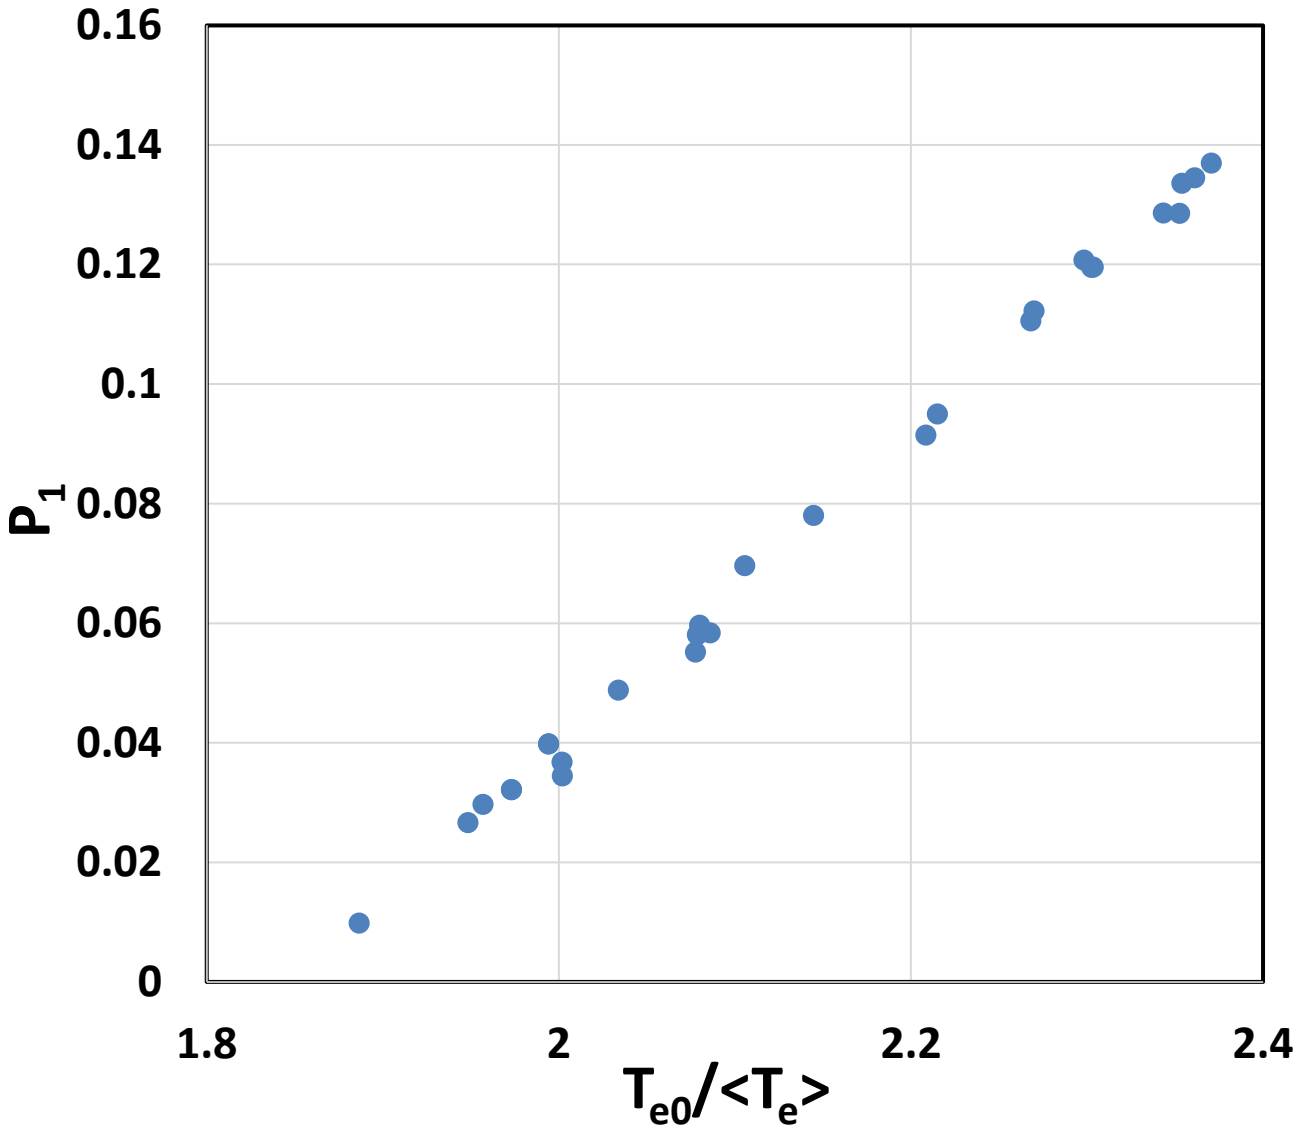
$$T_{Edge} = (T_{EdgeL} + T_{EdgeR})/2$$

$$P_1 = (T_{Core} - T_{Edge})/T_{Edge}$$

P_1>0 when profile is peaked
P_1<0 when profile is hollow

Radial windows can be optimized for specific scenarios

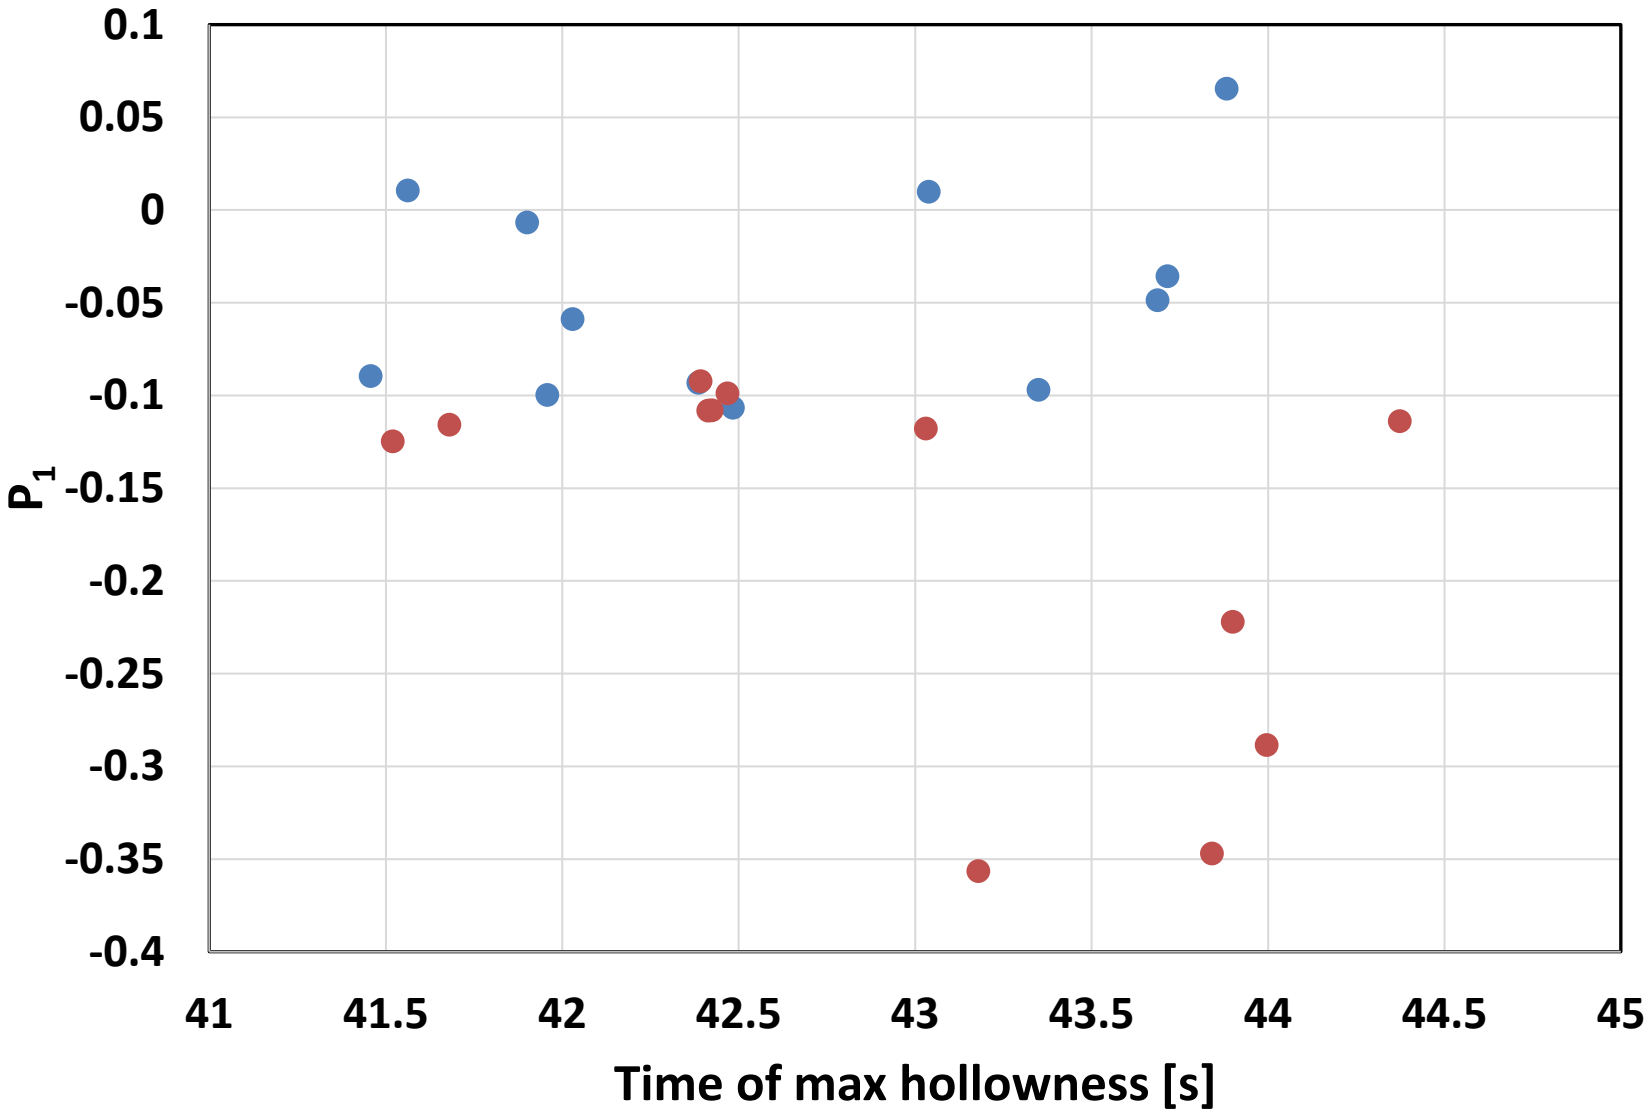
P_1 correlates with T_e peaking



Discharges from 2015 M_{eff} scan

Quantities averaged over [1.5, 3.5] s

P_1 correlates with disruptions in ohmic ramp phase

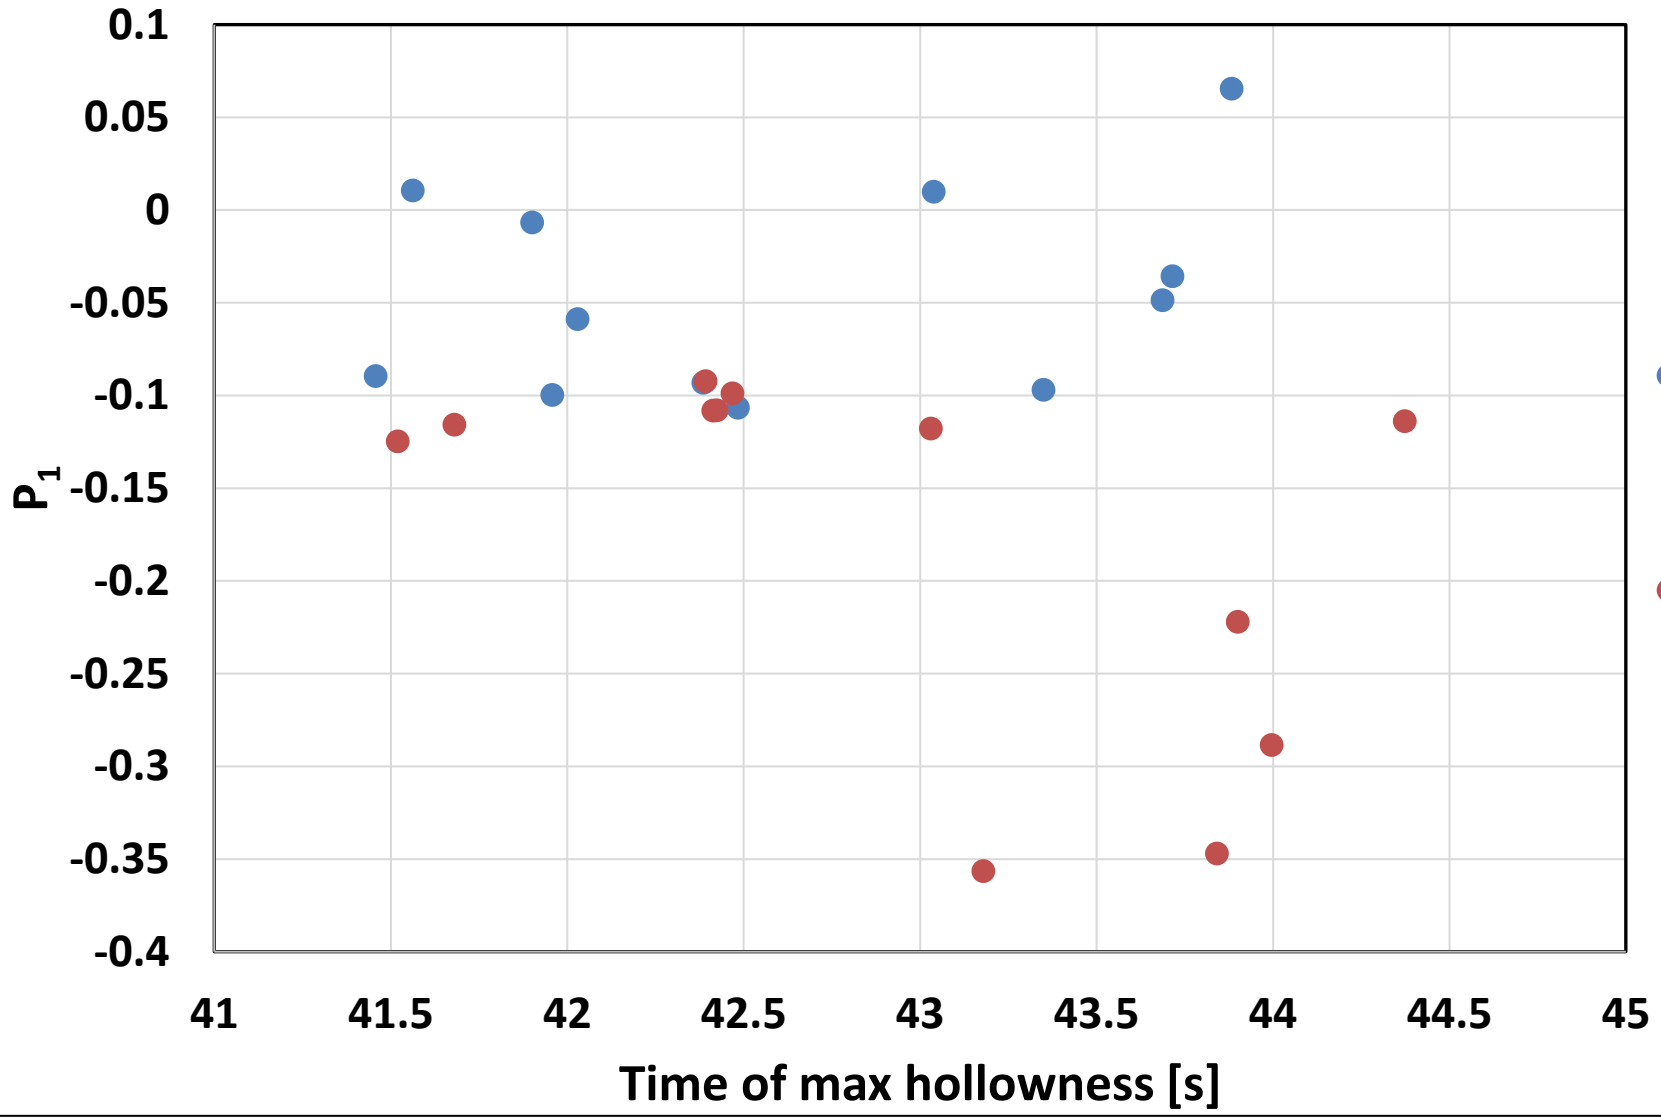


24 pulses from 2016 high β_N campaign

Non-disrupted

Disrupted

P_1 correlates with disruptions in ohmic ramp phase



24 pulses from 2016 high β_N campaign

Non-disrupted

Disrupted

"Peakedness" (P1) is not an unequivocal identifier for disruptions, but is definitely correlated.

Useful metric to avoid disruptions.

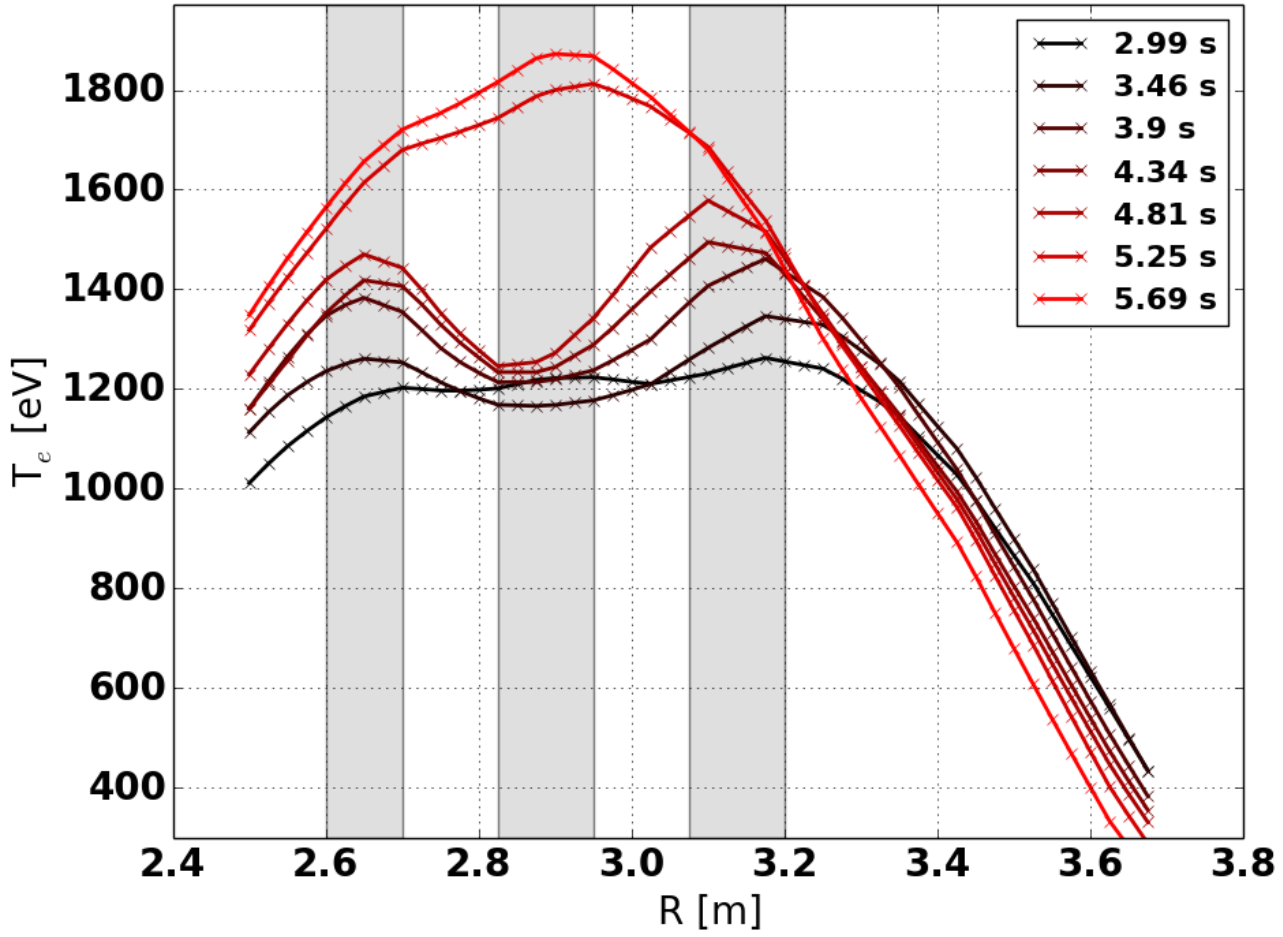
High β_N scenario ramp-up: disruption

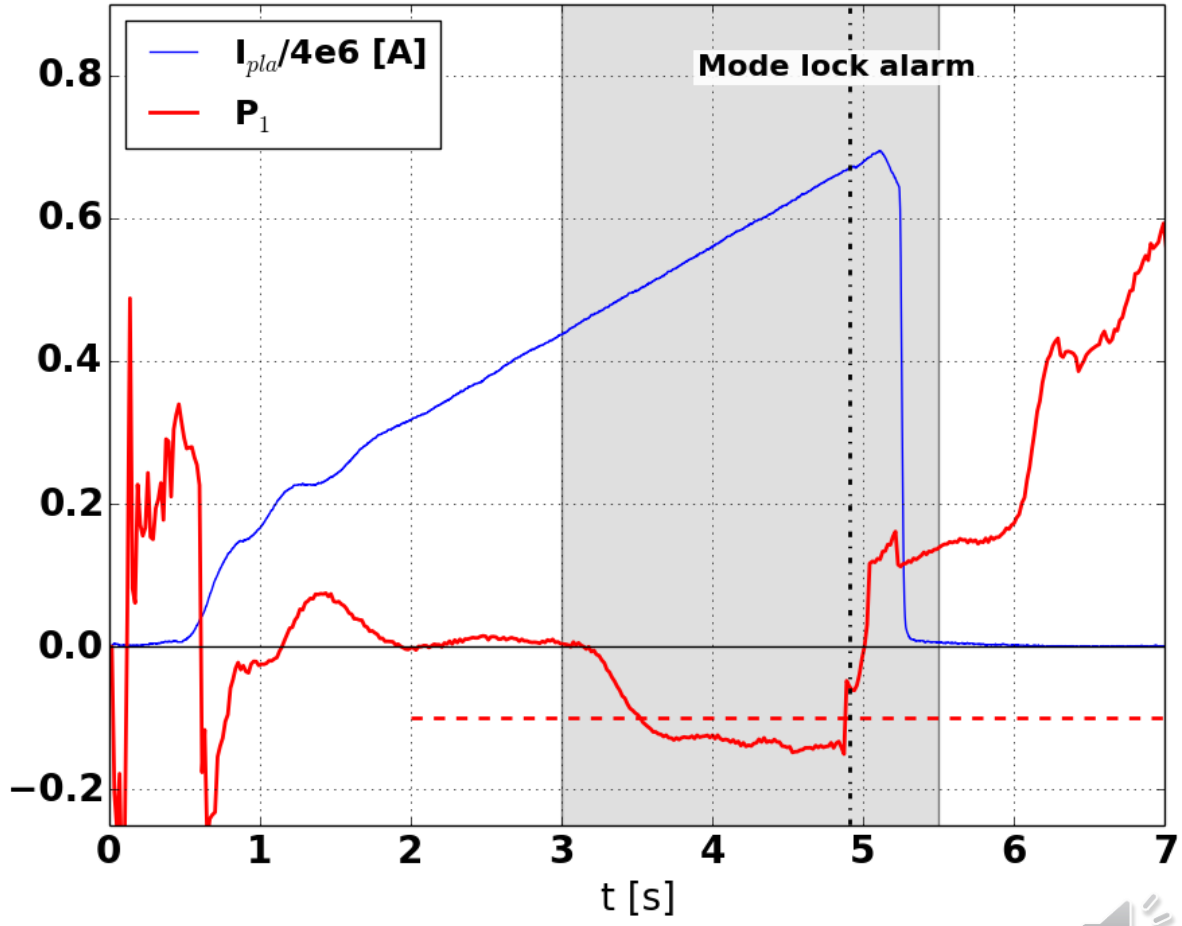
94065

I_p = 2.2 MA, B_T = 2.8 T

From 2016 high β_N disruptions, a controller is defined:

P_1<-0.1 for >20 ms in [3 5.5] s → Soft stop





High β_N scenario ramp-up: safe termination

95252

I_p = 2.2 MA, B_T = 2.8 T

Applied from August 2019 (>150 pulses).

When triggered, always led to safe termination (11/145)

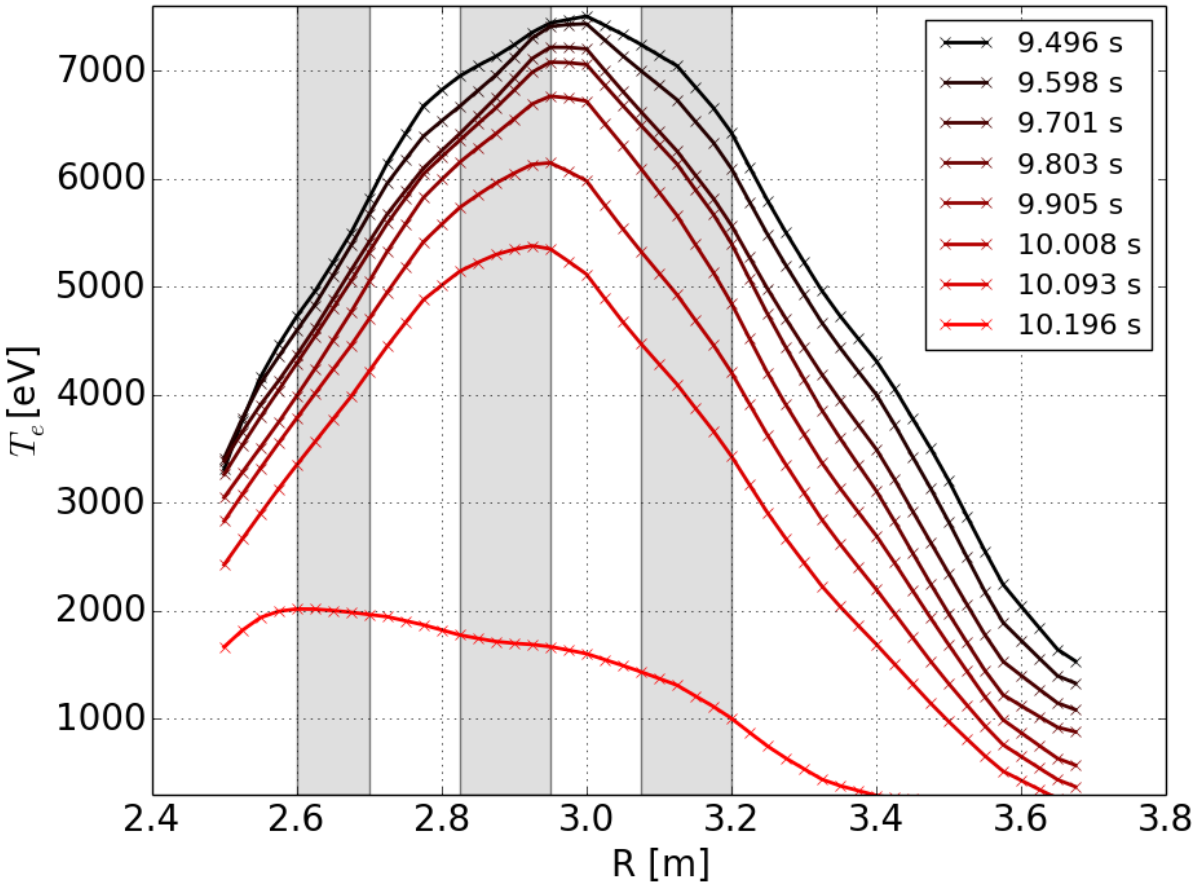
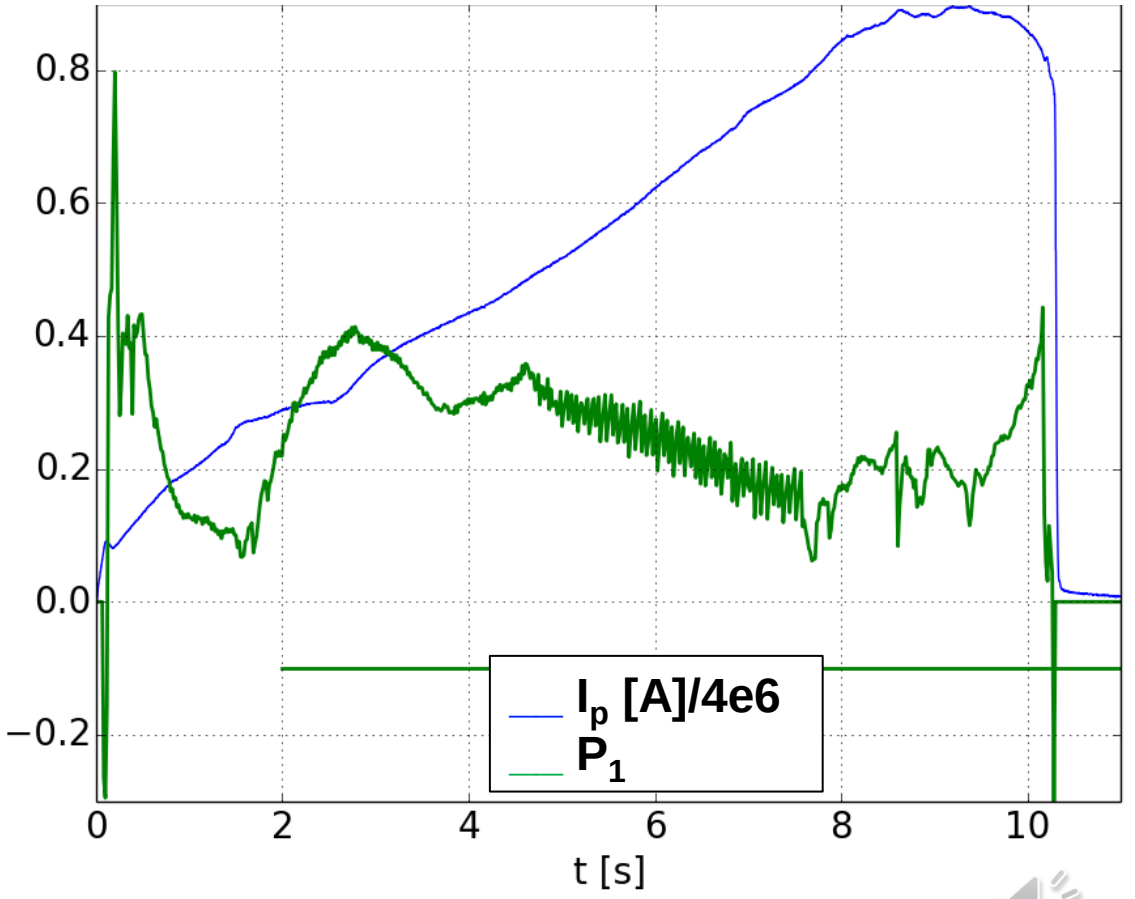
Outer core logarithmic gradient as metric for edge cooling

96483

I_p = 3.5 MA, B_T = 3.3 T

Edge cooling is one of the typical steps in a disruption





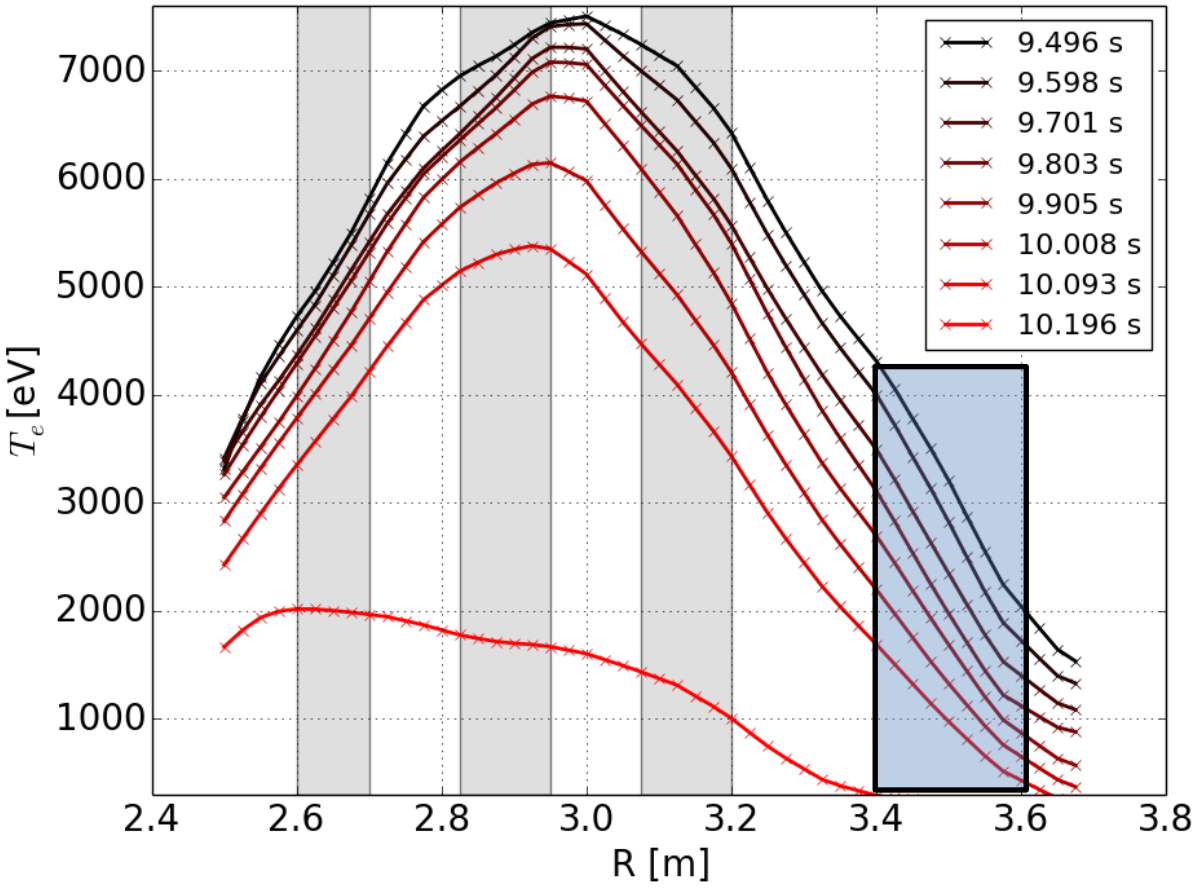
Other applications: metric for edge cooling

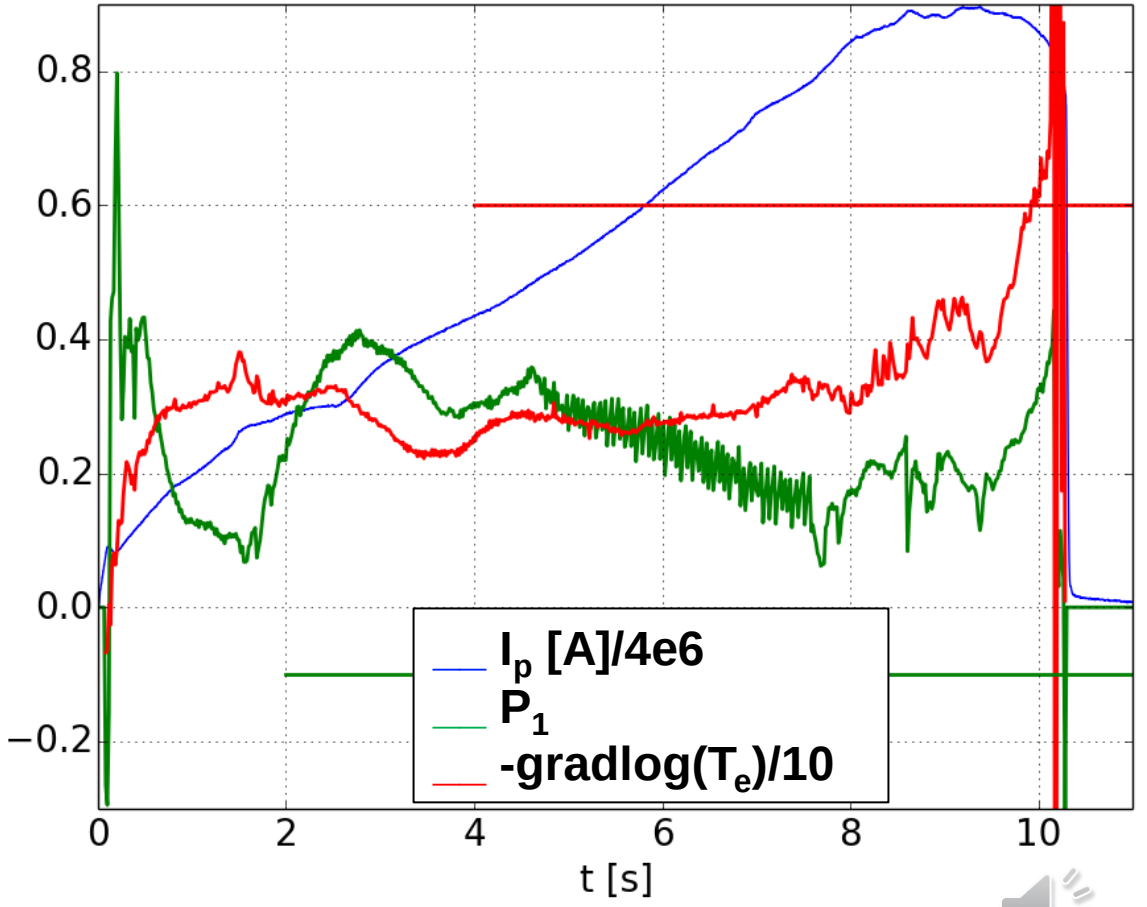
96483

I_p = 3.5 MA, B_T = 3.3 T

$$\frac{1}{T_e(R_{out})}\frac{dT_e}{dR}(R_{out})$$

$$R_{out} = 3.5\,m$$





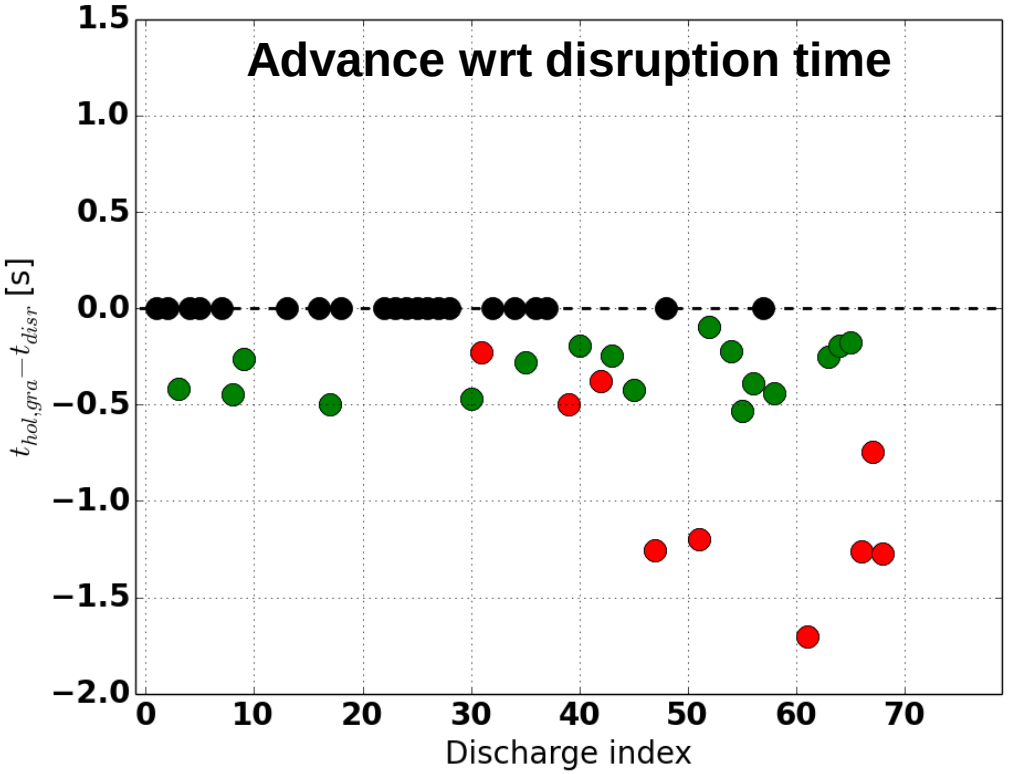
Other applications: plasma terminations

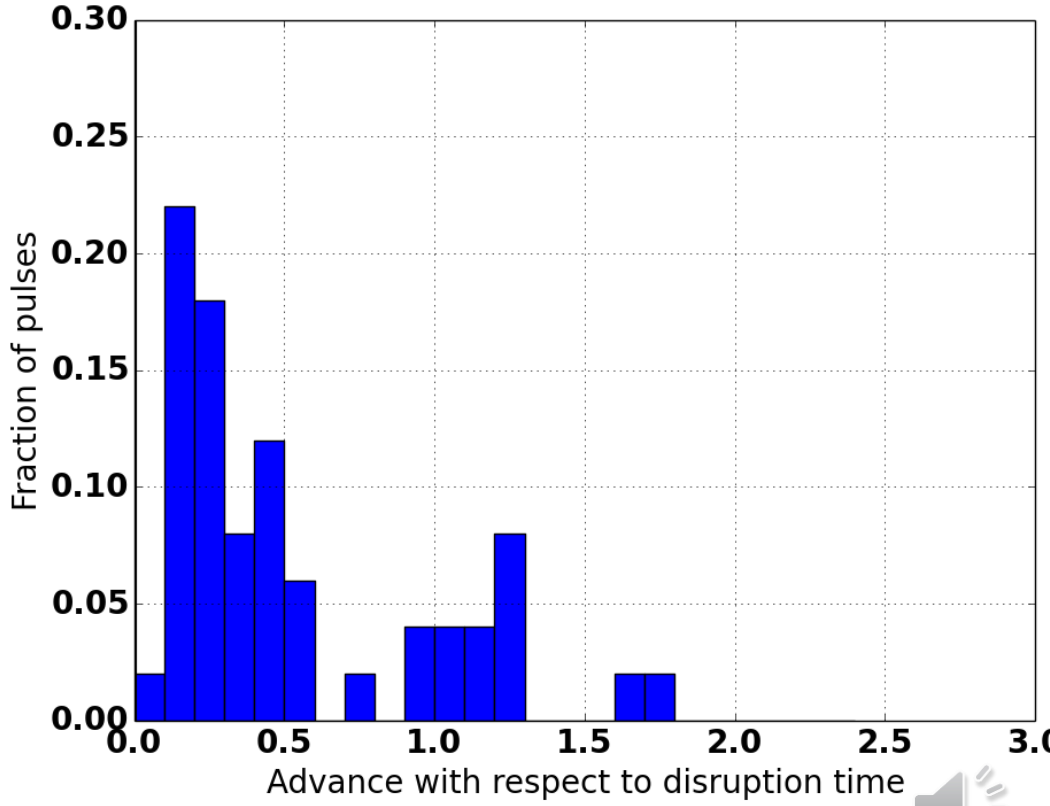
P1 and outer core gradient were compared to the existing alarms used at JET in plasma terminations.

They identify most disruptions with variable advance.

53 pulses from JET baseline experiments (2019-2020)

- **Gradient**
- **Hollowness**
- **False negatives**





Other applications: plasma terminations

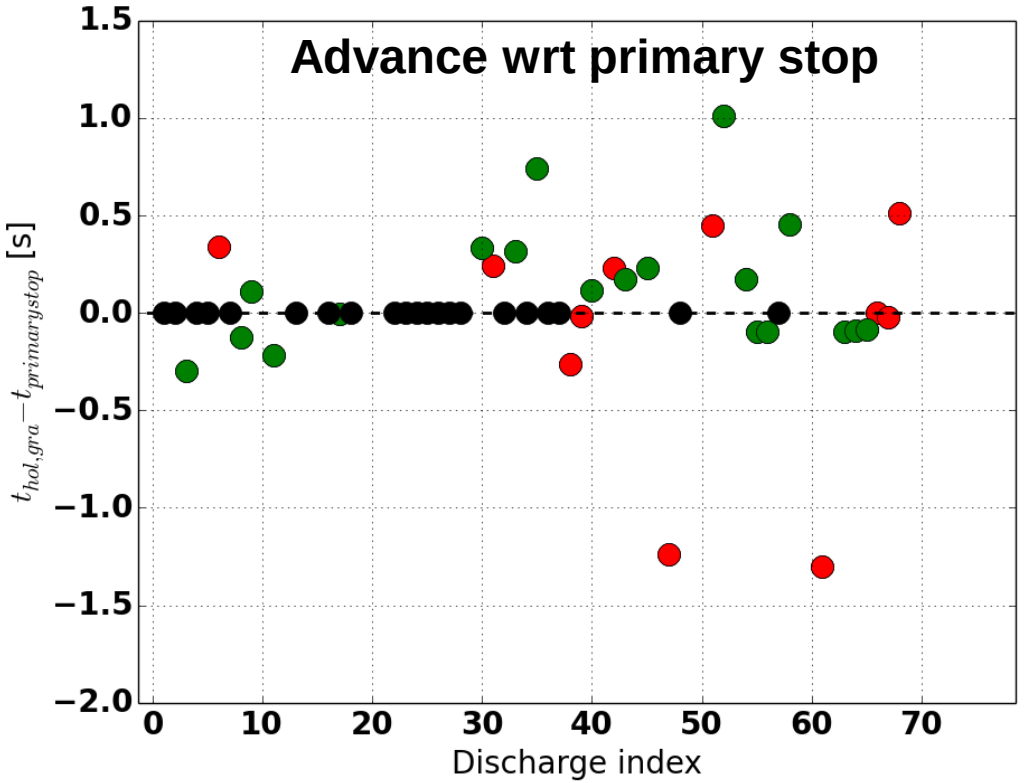
P1 and outer core gradient were compared to the existing alarms used at JET in plasma terminations.

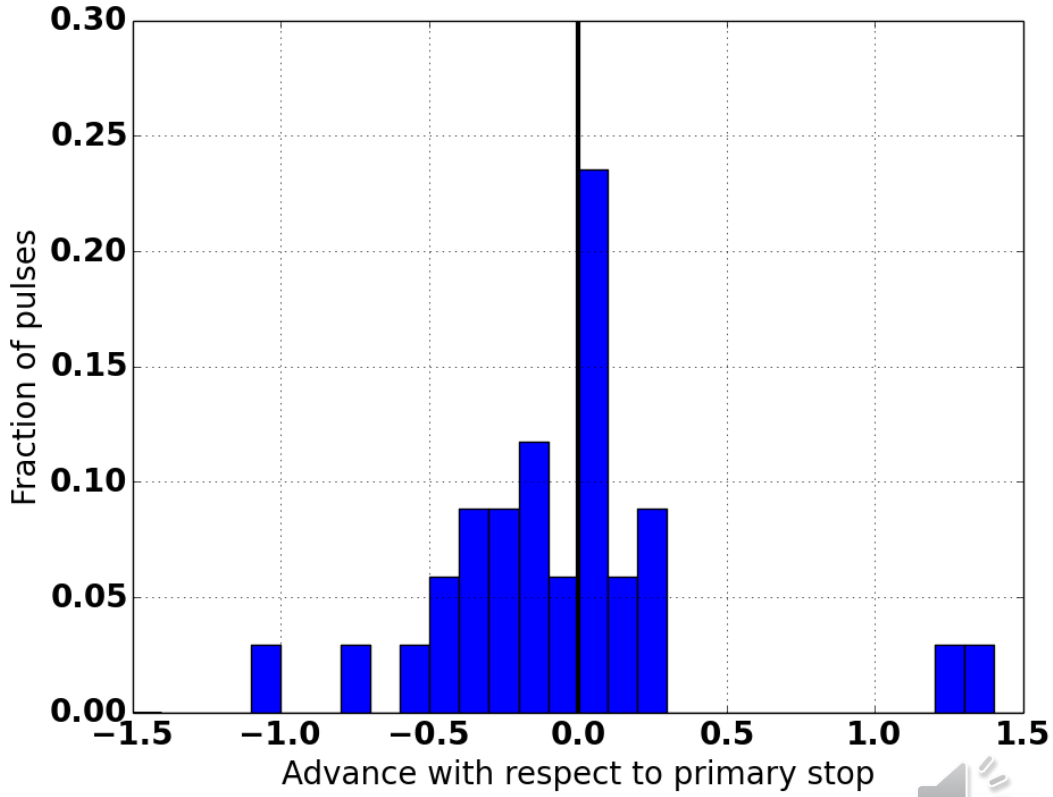
They identify most disruptions with variable advance.

In several cases, earlier than current alarms

53 pulses from JET baseline experiments (2019-2020)

- **Gradient**
- **Hollowness**
- **False negatives**





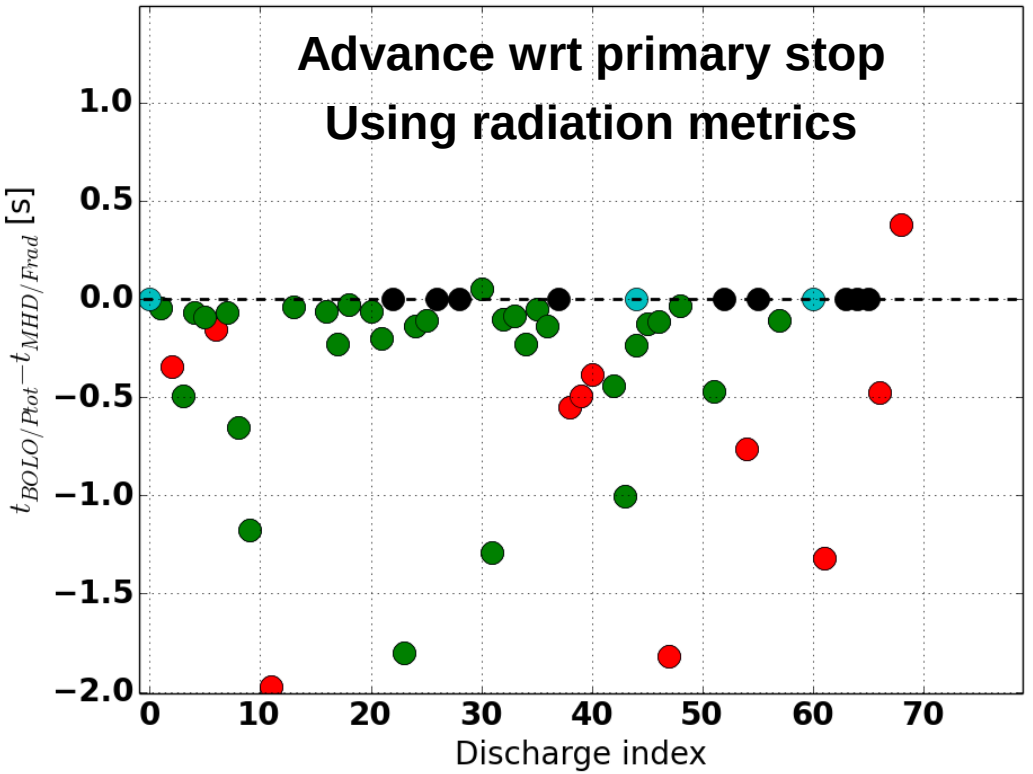
Future applications: combination with radiation metrics

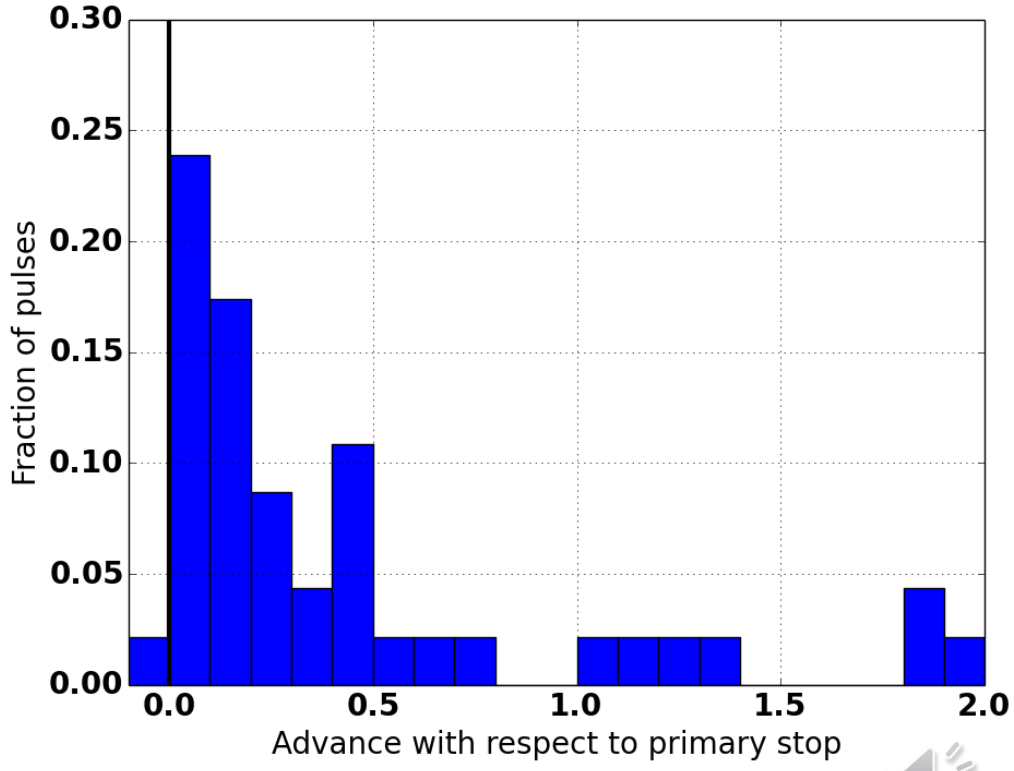
Interesting results were obtained combining with radiation metrics based on bolometry tomographic inversion: $P_{rad,core}/(P_{RF}*P_1)$ and $P_{rad,out}/P_{tot}$

Very good advance with respect to existing alarms.

53 pulses from JET baseline experiments (2019-2020)

- $P_{rad,out}/P_{tot}$
- $P_{rad,core}/(P_{RF}*P_1)$
- **False negatives**
- **False positives**





JET CCFE CULHAM CENTRE FOR FUSION ENERGY EPFL Swiss Plasma Center

Future applications: combination with radiation metrics

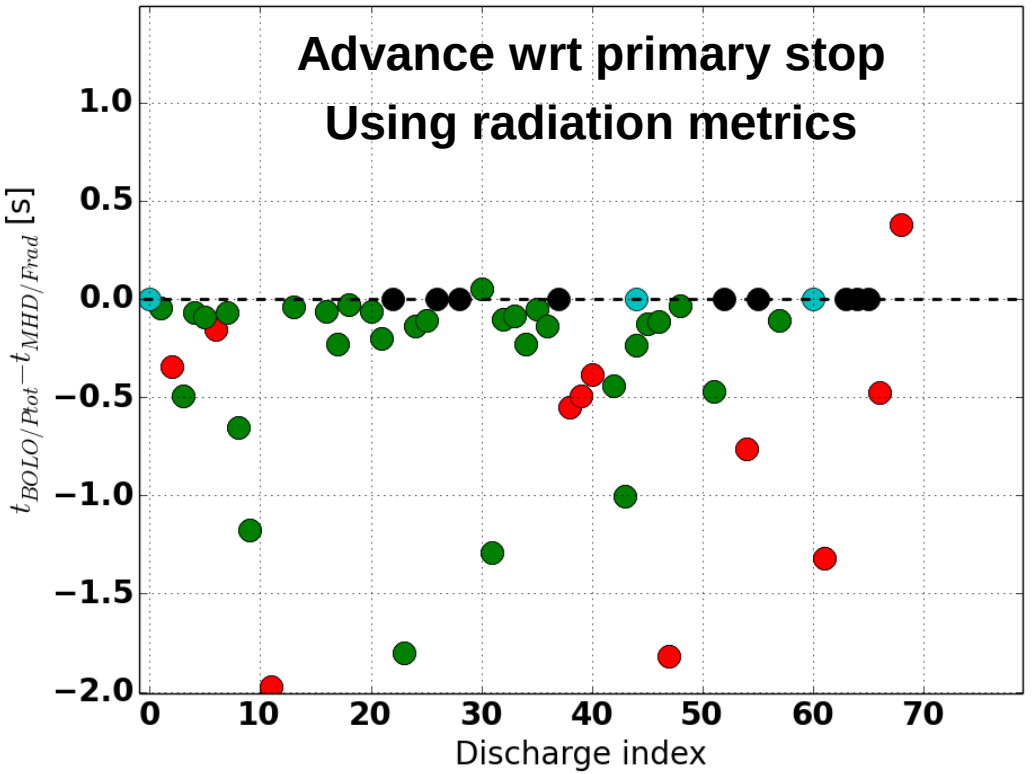
Interesting results were obtained combining with radiation metrics based on bolometry tomographic inversion: $P_{rad,core}/(P_{RF}*P_1)$ and $P_{rad,out}/P_{tot}$

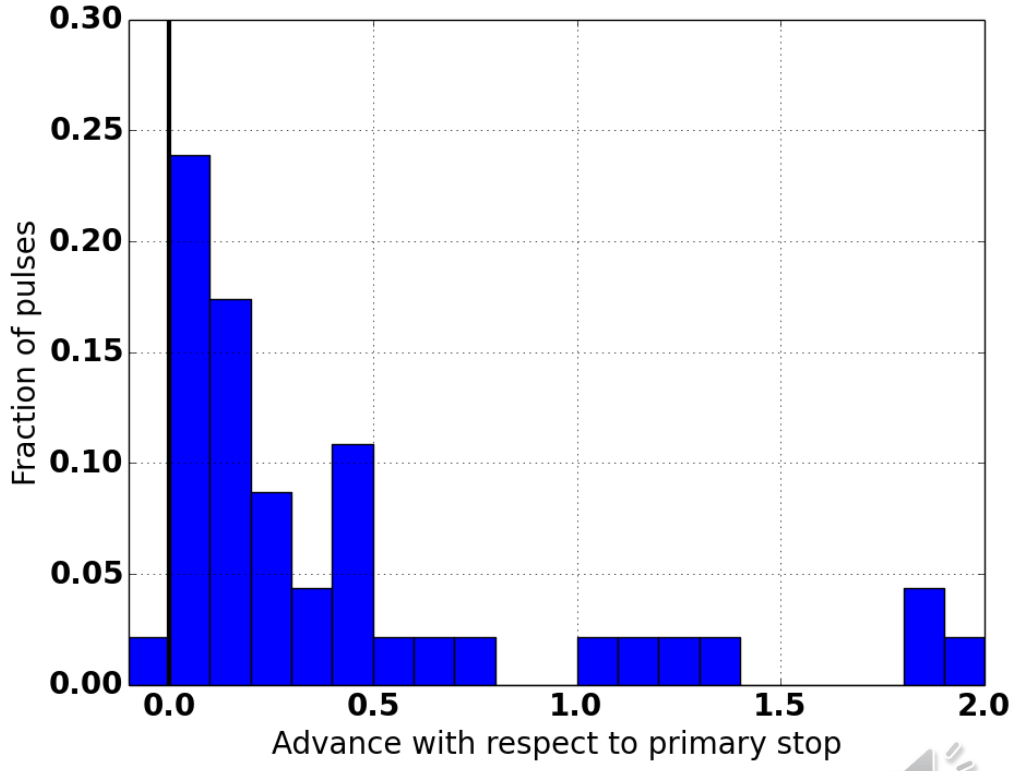
Very good advance with respect to existing alarms.

Particularly useful to separate core and edge radiation events

53 pulses from JET baseline experiments (2019-2020)

- $P_{rad,out}/P_{tot}$
- $P_{rad,core}/(P_{RF}*P_1)$
- **False negatives**
- **False positives**





Conclusions

- **JET ECE X-mode interferometer now produces T_e profiles in real time**
  - First real-time application of ECE interferometers
  - Profiles every 16 ms, <1 ms for processing
  - Simple, robust definitions for peakedness and outer core gradient metrics

- **First application: hollowness detection in high β_N ramp-up**
  - Pre-emptively identify duds: avoid running bad pulses and avoid disruptions during current overshoot
  - Reliably employed in high β_N pulses since August 2019

- **Other applications: disruption avoidance in baseline scenario termination**
  - Peakedness gives substantial advance in certain cases. Promising in combination with bolometer tomography [*see also D. R. Ferreira talk at this conference*]

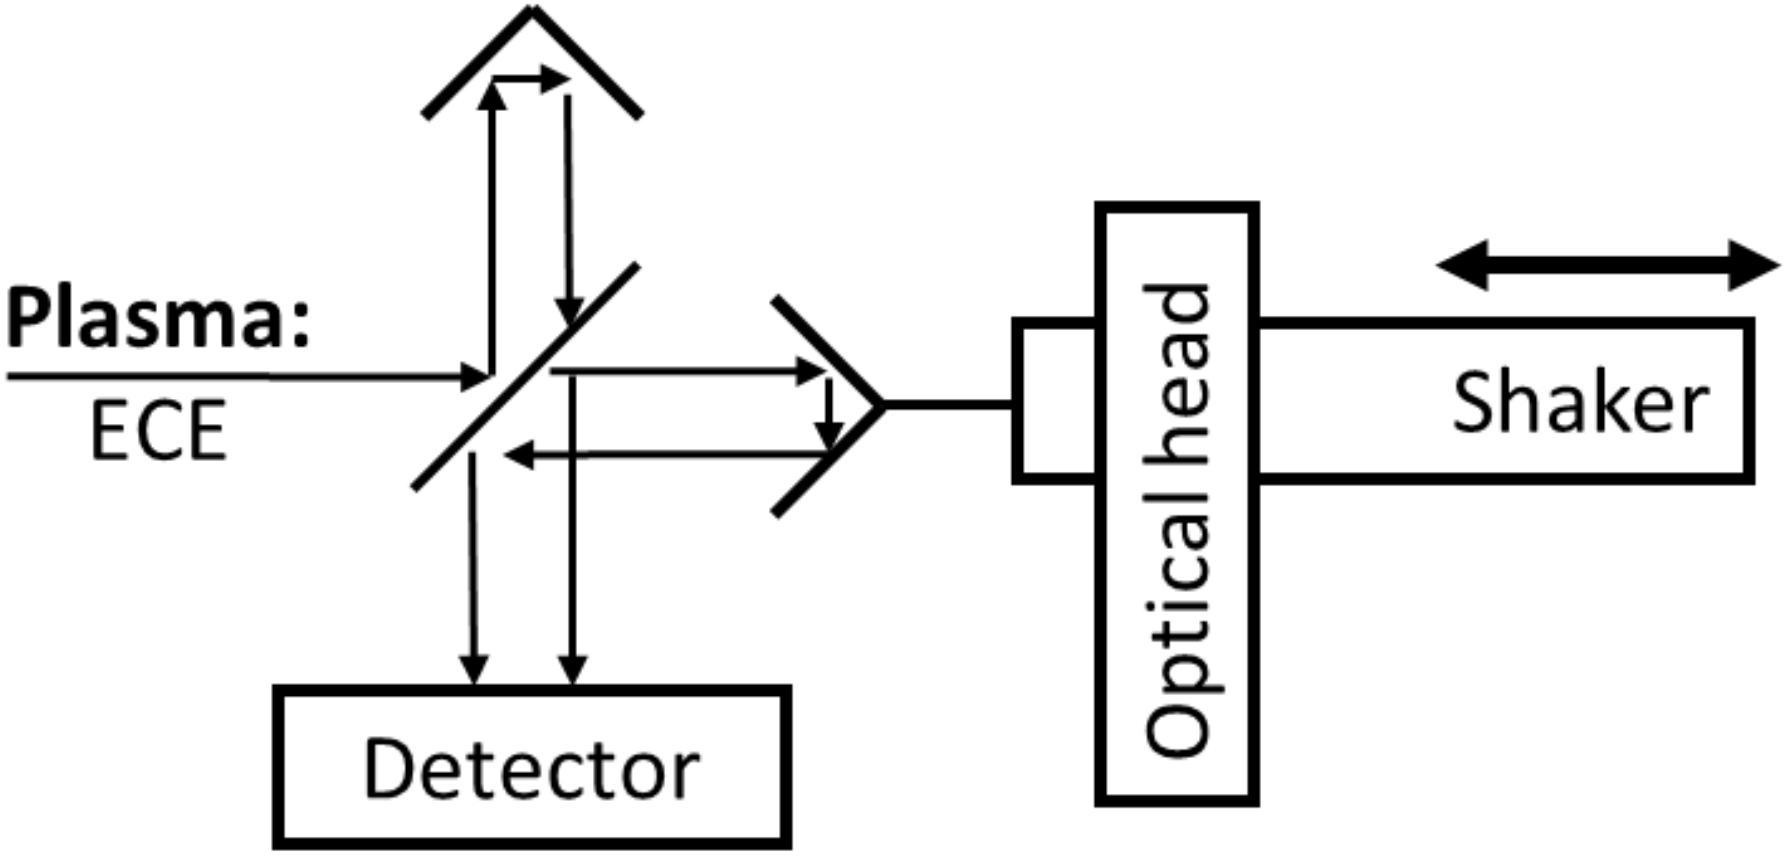
Interferometer schematics

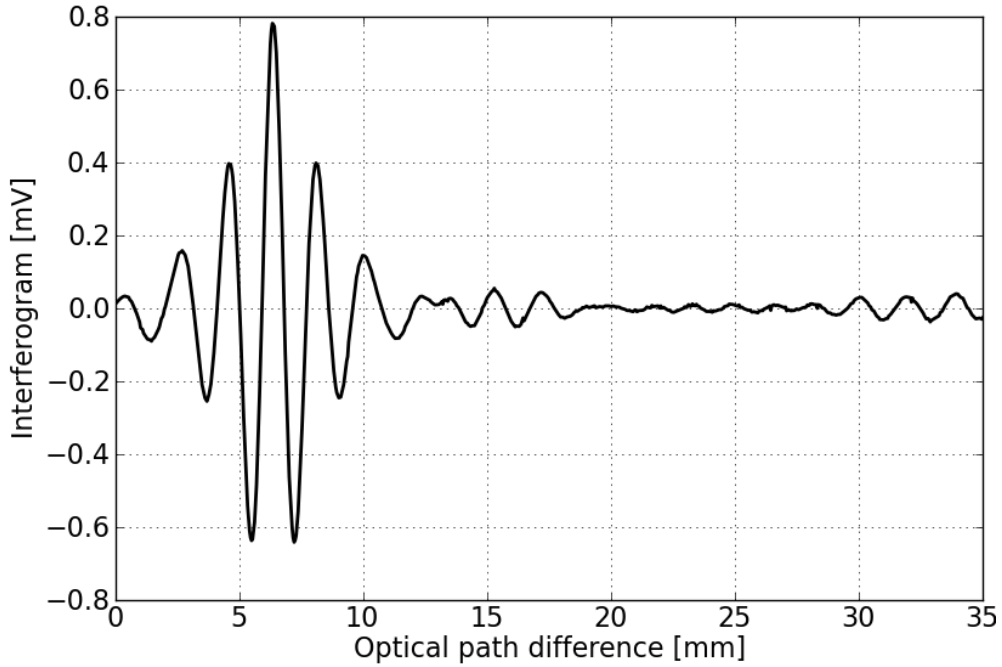


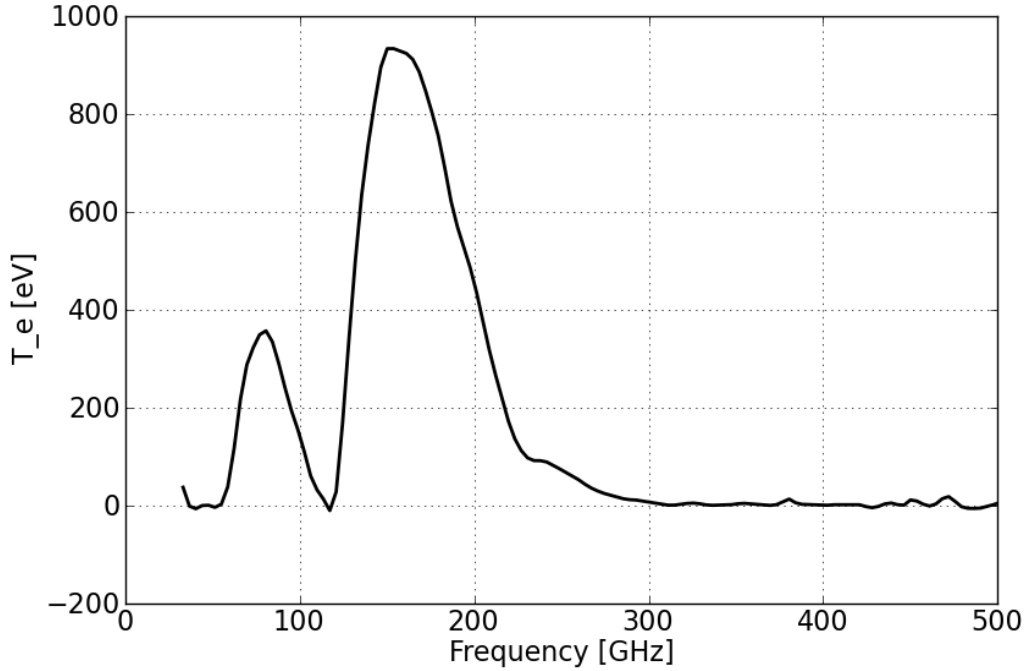
Fourier transform of interferogram is $T_{rad}(f)$

Raw interferogram — Amplification — Fourier transform

$$V_R(x_i) = 2A \int T_{Rad}(f) C_T(f) \cos\left(2\pi \frac{f}{c} x_i + \alpha\right) \mathrm{d}f + B$$

Opt. path difference — Calibration — Phase — Background





T_e profiles derive from magnetic reconstruction

$$f_{ECE} = \frac{eB}{2\pi me} \qquad B(R) = \sqrt{B^2_{tor}(R) + B^2_{pol}(R)}$$

No individual channels:
Whole spectra are available for every interferogram

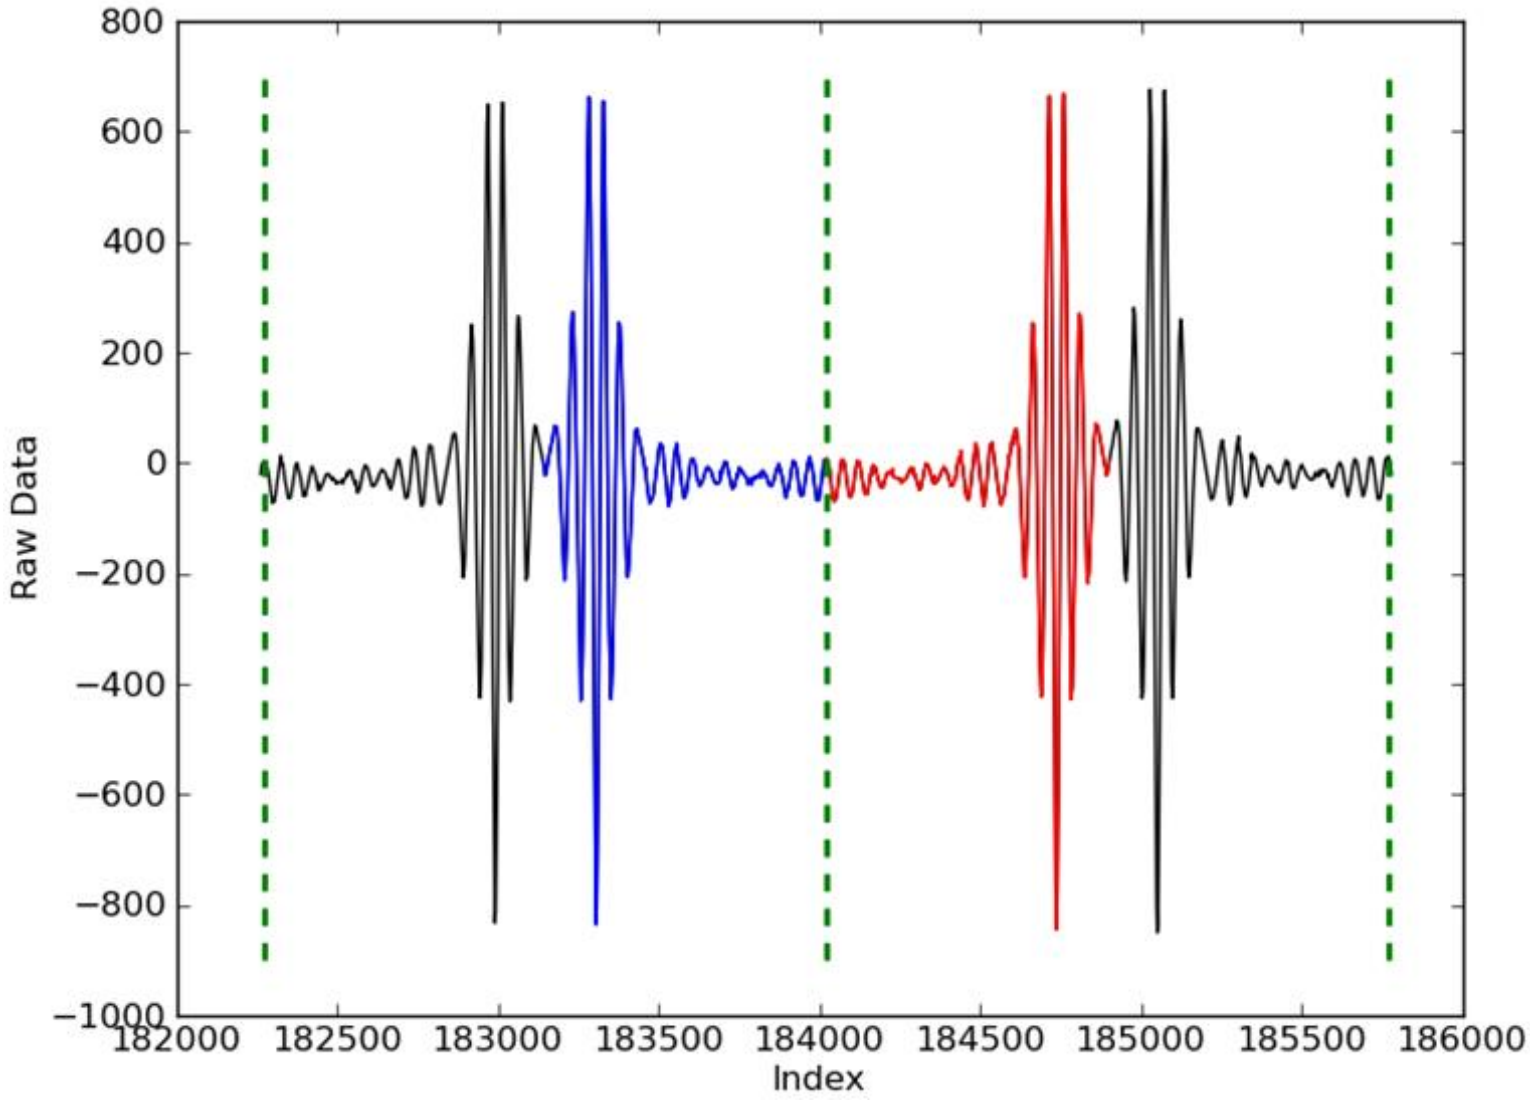
RT data processing: approximated B field

Each interferogram is isolated and processed separately.
~1 ms processing for each interferogram

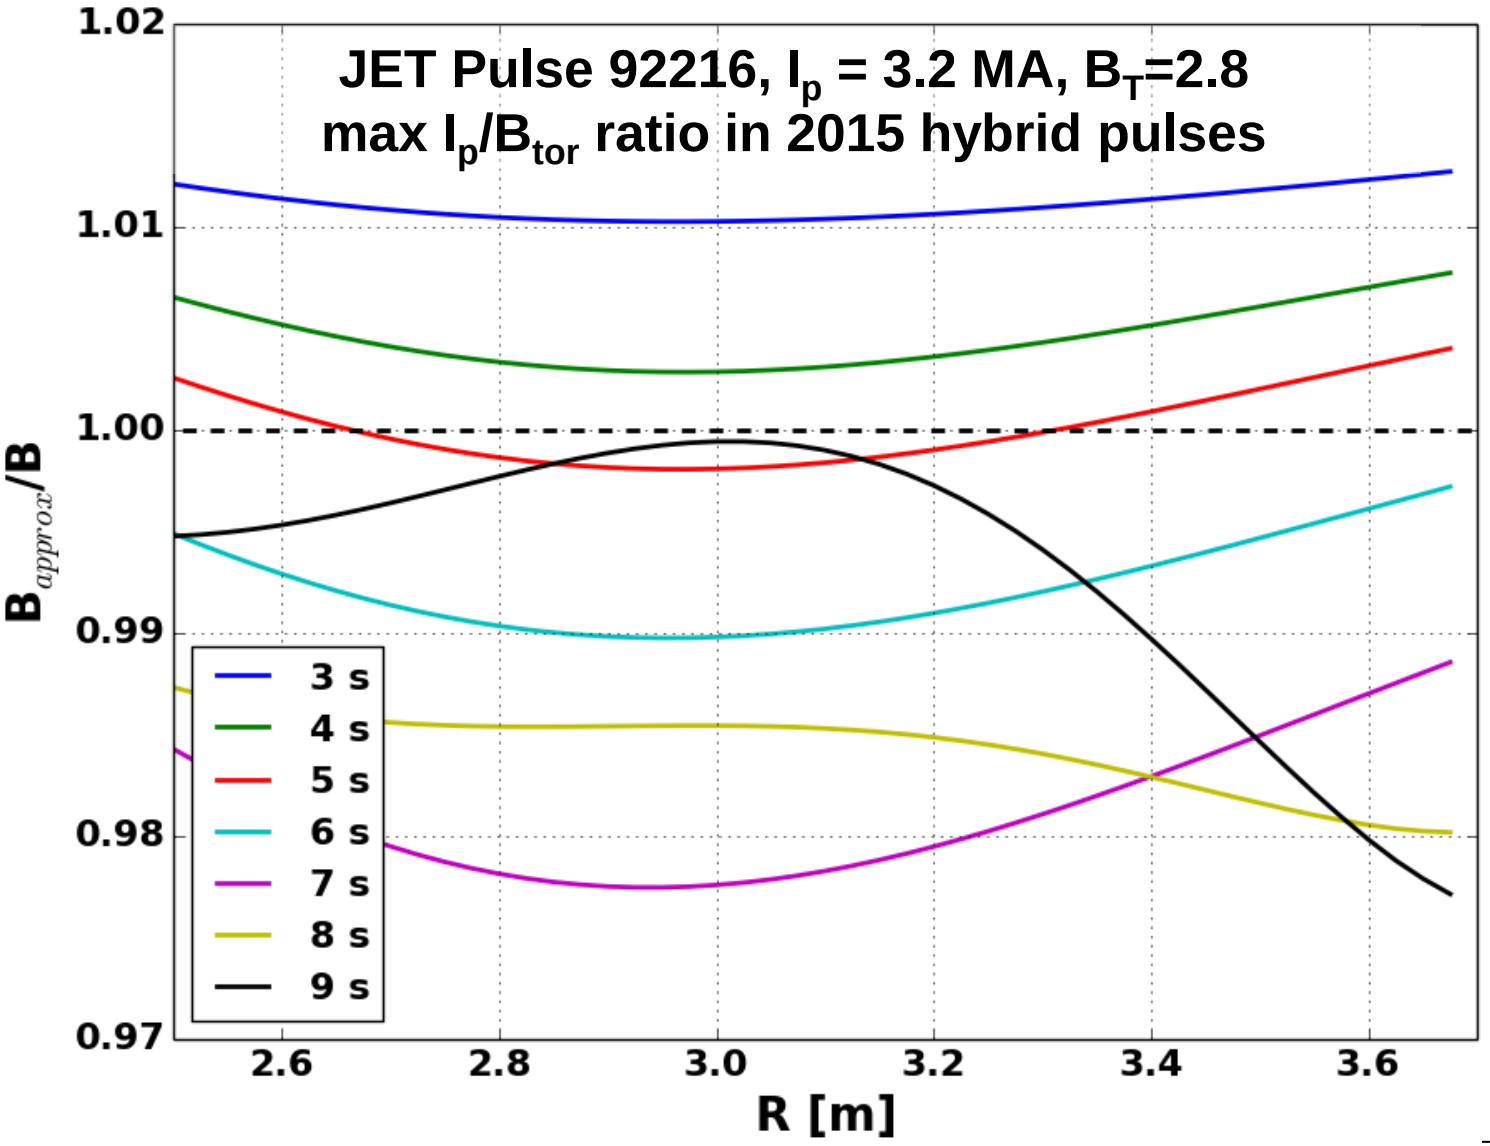
Approximation: $\boldsymbol{B_{approx} = B_{tor}}$

Only $\mathbf{I_{tfc}}$ required as ext. input, no equilibrium reconstruction.

Best results are obtained for low I_p/B_{tor} pulses.
Interesting for current ramp phase



B field approximation: good results during current ramp



$$B_{approx} = B_{tor} = B_{tor,R_0}\frac{R_0}{R}$$

$$B_{tor,R_0} = \frac{\mu_0}{2\pi}\frac{I_{tfc}}{R_0}N_{turns}N_{coils}$$

$$0.97 < \frac{B_{approx}}{B} < 1.02$$

Small shift due to magnetic field approximation

$$f_{ECE} = \frac{eB_{simple}}{2\pi m_e}$$

Agreement depends on I_p/B_{tor}

94945

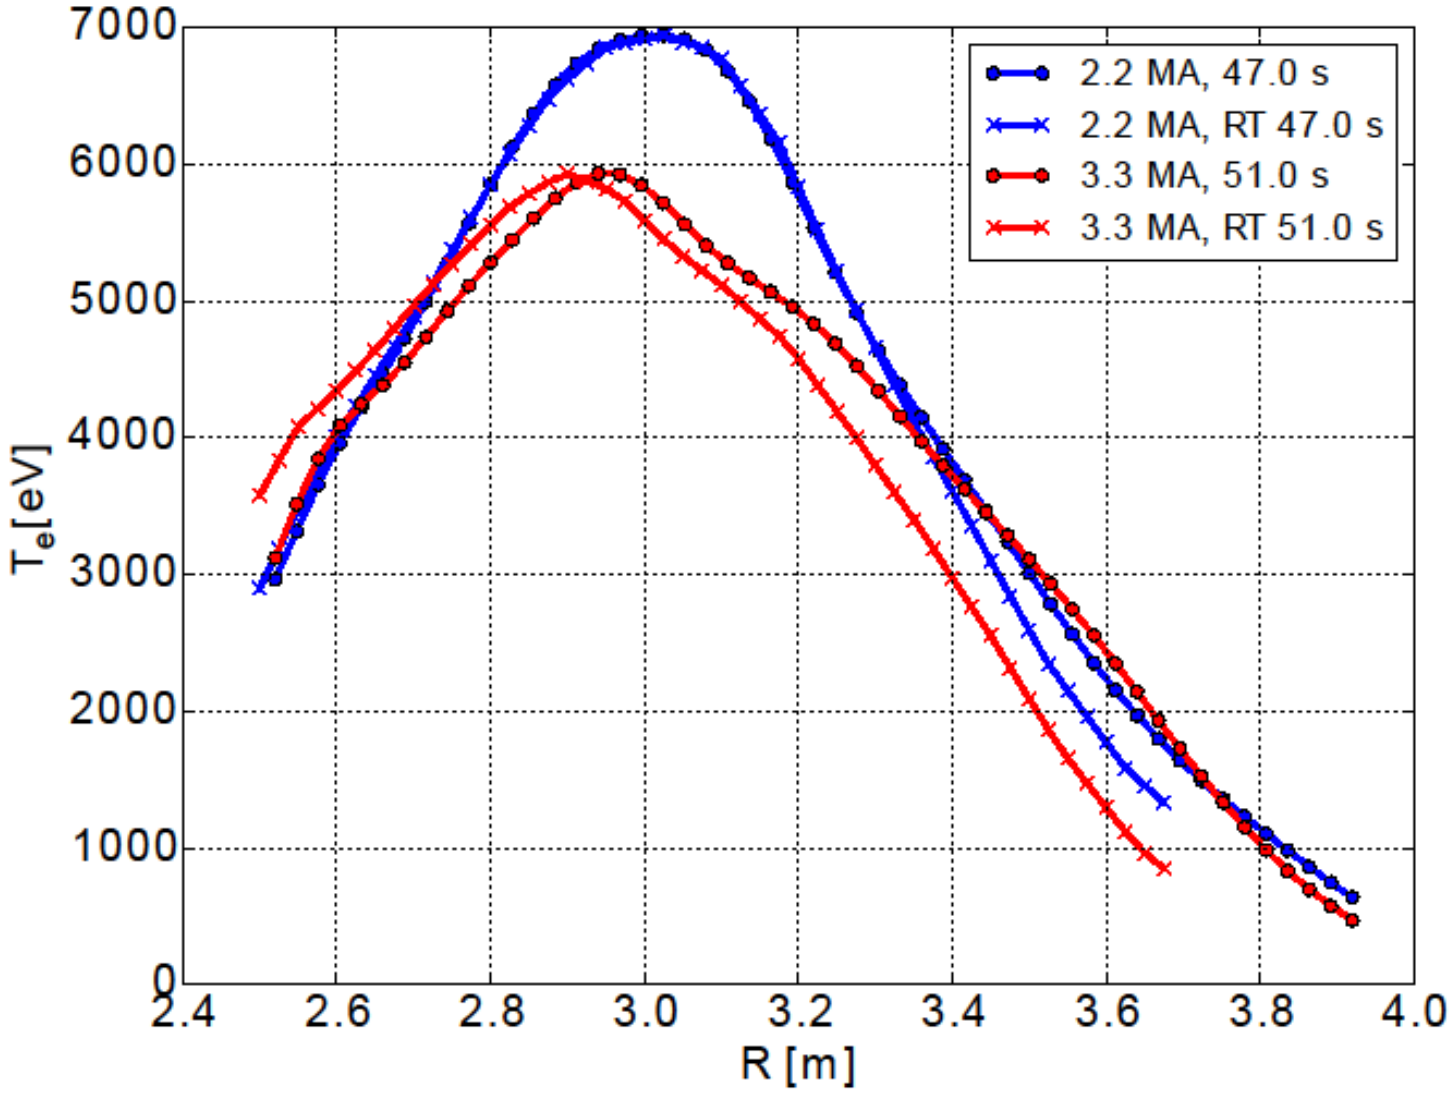
I_p = 2.2 MA, B_T = 2.8 T

(<3 cm shift)

94788

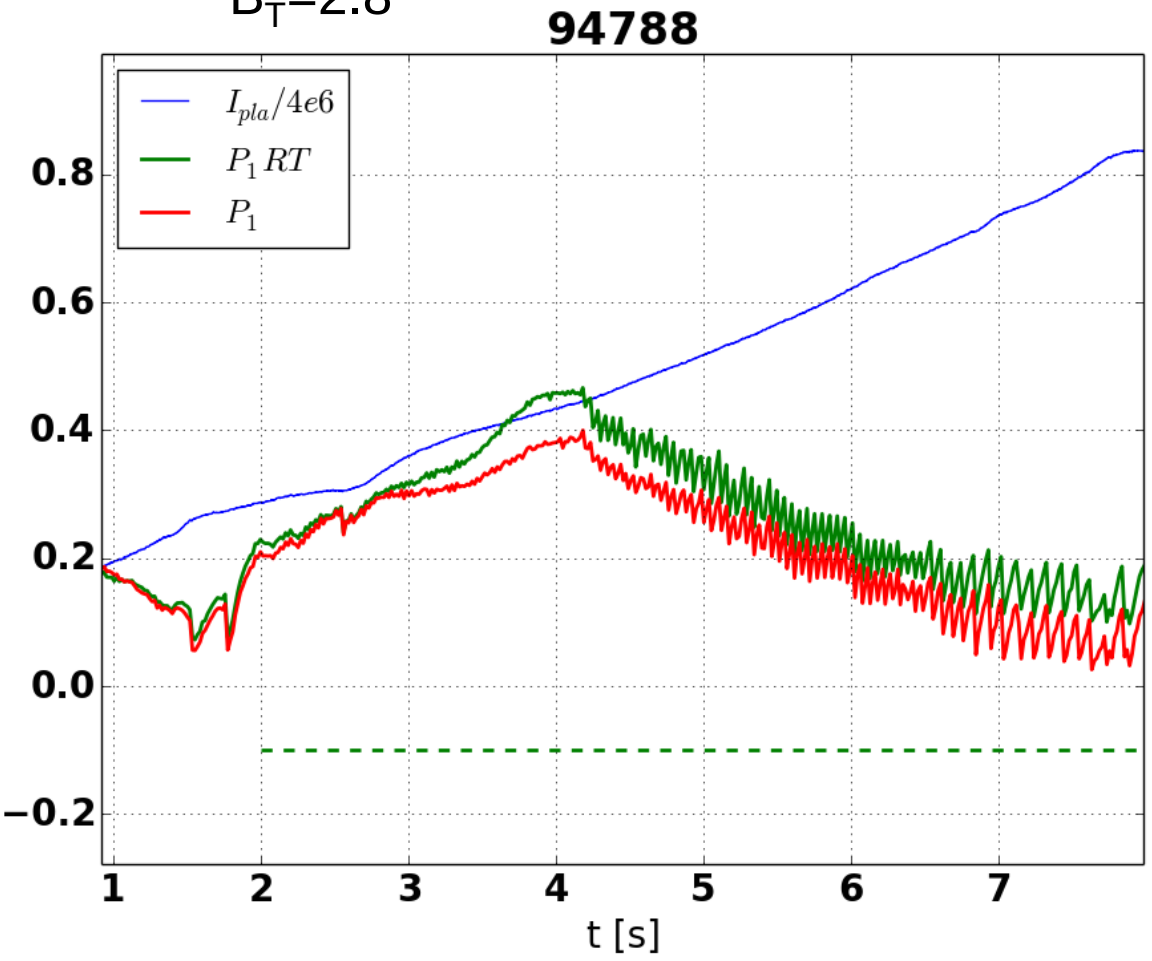
I_p = 3.3 MA, B_T = 2.8 T

(5/15 cm core/LFS shift)

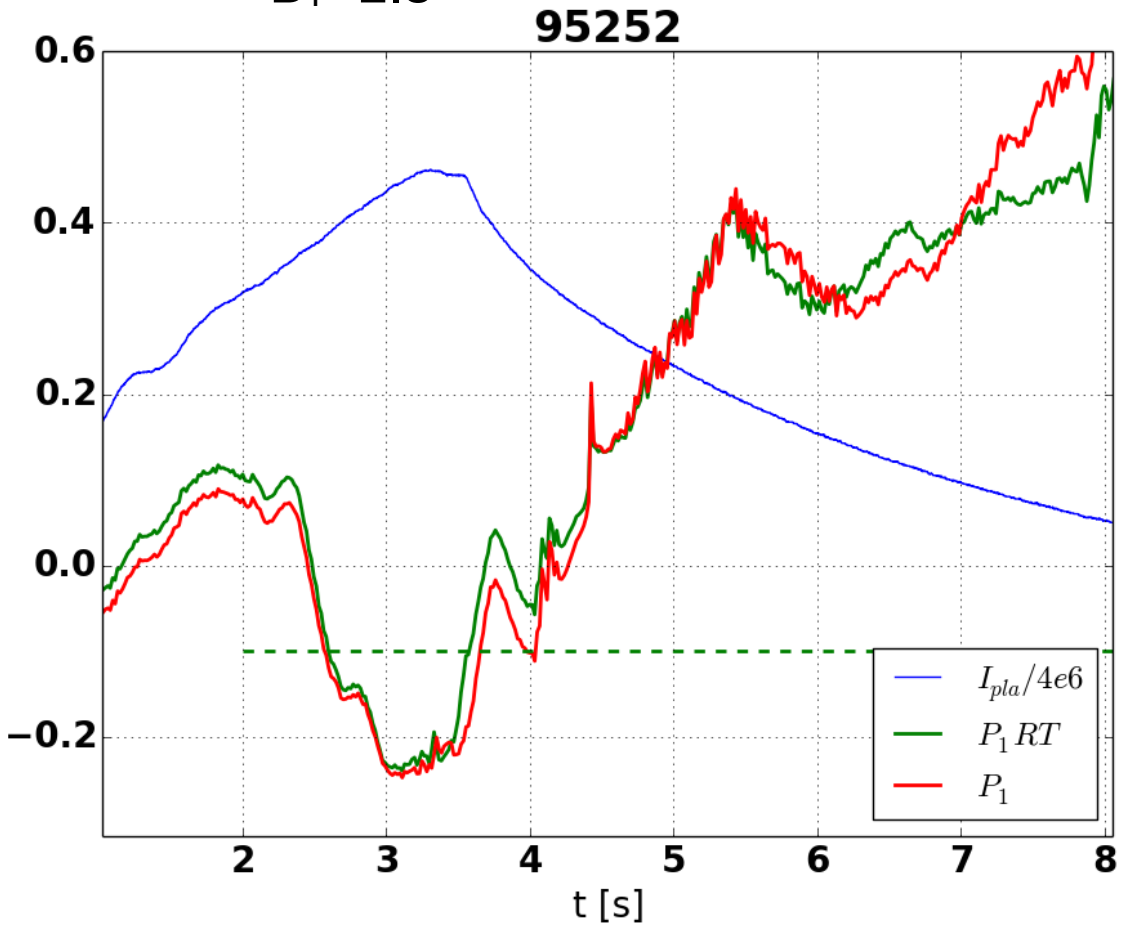


Small error between approximation and ppf

Pulse 94788
I_p 3.3 MA
B_T=2.8



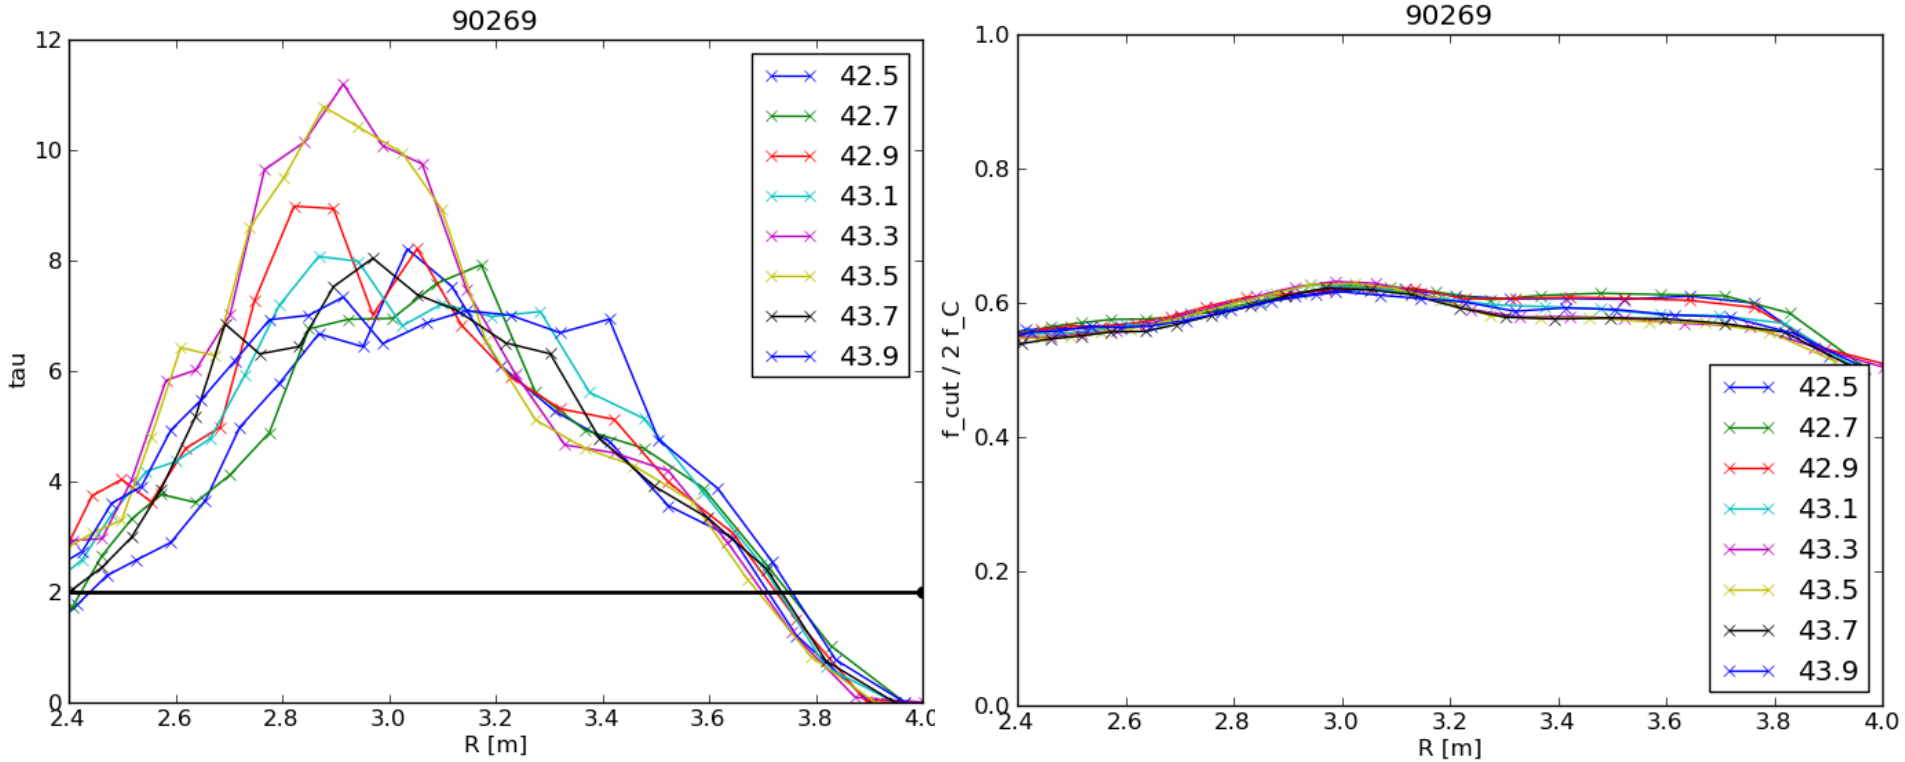
Pulse 95252
Ip 2.2MA Hybrid
B_T=2.8



Cutoff/optical depth pose no problem in ramp

Optical depth (τ) > 2 is considered sufficient for $T_{rad} = T_e$

Issues may arise for high density phases before disruptions



36

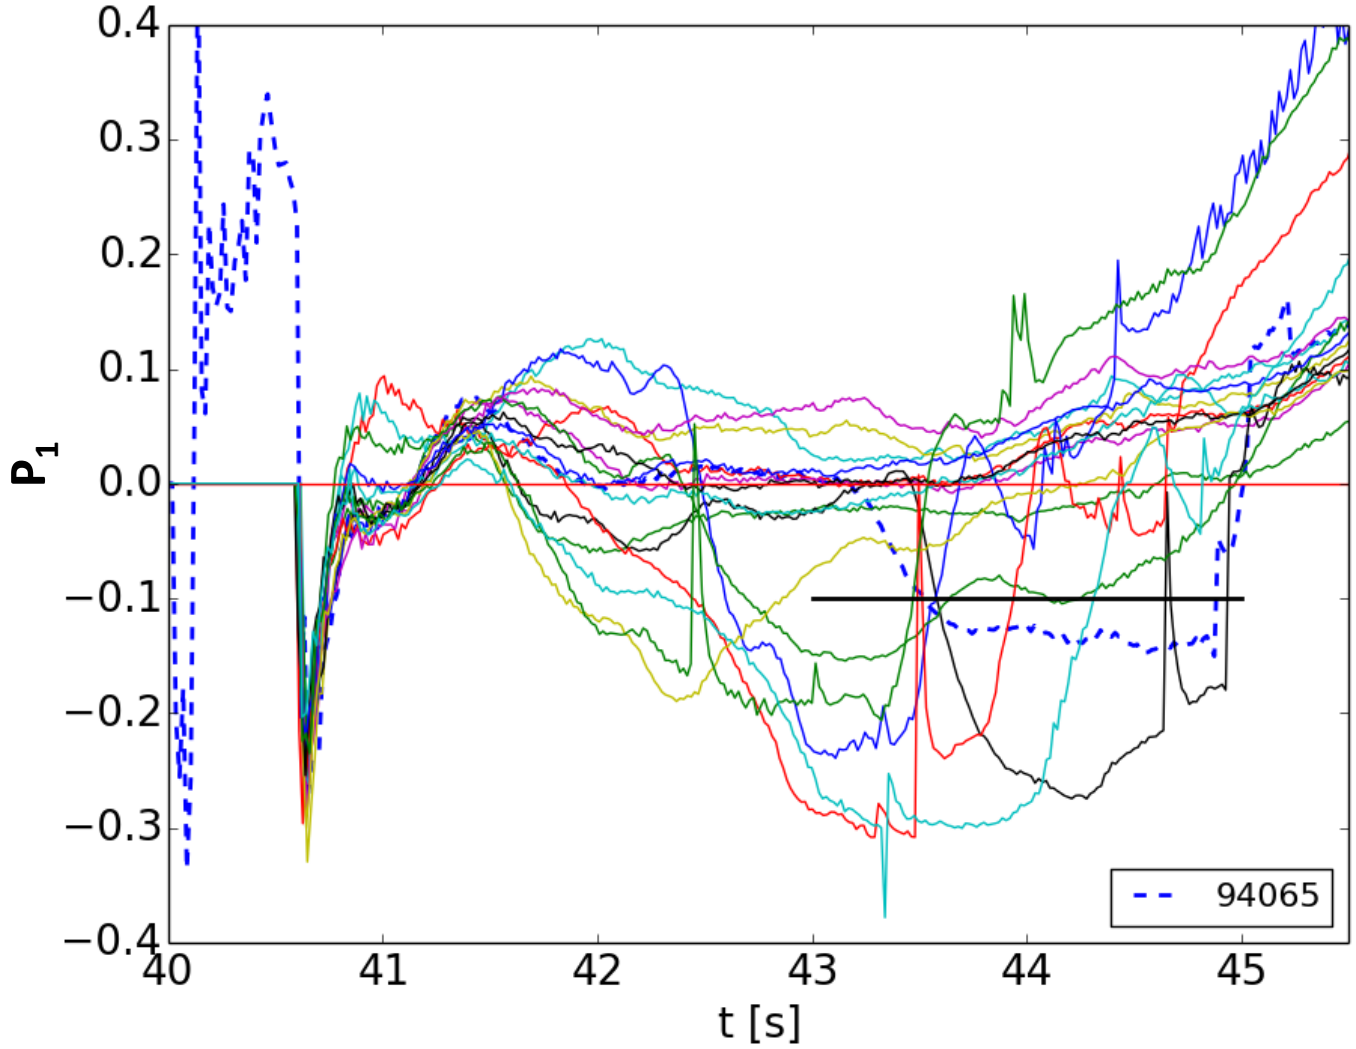
First applications: hybrid pulses ramp-up phase

Hybrid pulses at JET: improved confinement wrt IPB98(y,2) scaling

- High β_N
- Rely on wide low magnetic shear region in the plasma core at q=1
- q-profile optimized during current ramp-up phase
  - Often ending with a current overshoot
  - Sensitive to main ion mass [*C. D. Challis et al, Nuclear Fusion, 2020*]

- Sometime present hollow temperature profile during the current ramp-up as a consequence of impurity accumulation.
  - Can cause double tearing modes: terminated by mitigation system, but potential of high current disruptions (>3MA)

M18-02 tested the system with success



17/09 session:
6/16 pulses triggered protection

All landed safely

Not known if they would all have been disruptions.

Future applications: combination with radiation metrics

Interesting results were obtained using radiation metrics based on bolometry tomographic inversion: **$P_{rad,core}/P_{tot}$** and **$P_{rad,out}/P_{tot}$**

Very good advance with respect to existing alarms.

53 pulses from JET baseline experiments (2019-2020)

- **$P_{rad,out}/P_{tot}$**
- **$P_{rad,core}/P_{tot}$**
- **False negatives**
- **False positives**
