# Modeling a Lithium Vapor **Box Divertor and Resulting Ion Flows on NSTX-U using SOLPS**

Author: Eric Emdee

IAEA 4th Technical Meeting on Divertors

Vienna, Austria November 8th, 2022

Advisor: Rob Goldston

#### Introduction: Divertor Detachment Can Be Problematic

- Divertor detachment is necessary for future fusion devices to ensure PFC lifetime
- Divertor detachment with medium-Z impurities has the tendency to create a highly radiating region at the X-point
  - Can reduce core & pedestal performance
  - Heat flux reduction can be maintained at the cost of high Z<sub>eff</sub>
- Goal: create a detached divertor that confines radiation and impurities close to the target

#### Introduction: The Lithium Vapor Box

- The lithium vapor box seeks to detach via lithium vapor evaporation near the target, and condensation further upstream
- Original vapor box design imagines different chambers for condensation and evaporation
- A large focus of this work is determining the importance of the specific geometry to:
  - Keep radiation below X-pt
  - Keep impurities in box

#### **Modelling High Power Conditions**

 Low power lithium vapor box can have nearly non-existent upstream lithium fraction (Emdee et al. 2021)

 Moved to predictive modeling of high power NSTX-U H-mode shots using SOLPS

- 
$$P_{in} = 10 \text{ MW}$$
  
-  $q_{target}^{max} \sim 65 \text{ MW/m}^2$ 

4

# Set Up: Box to Slot Comparison

- Set up two divertor designs, one closer to the original vapor box design with a box and one a slot divertor geometry

#### Upstream Temperature Can Be Sustained With a Box Geometry <sup>150</sup> Box no puff Slot no puff

- The upstream temperature is unaffected by lithium evaporation if the divertor has a box geometry
- Slot sees upstream
  temperature degradation as
  lithium evaporation is
  increased
  - Corresponds to n<sub>Li</sub>/n<sub>e</sub>>0.1 upstream

#### Lithium Fraction Controlled Better in Box

- Upstream lithium content in the slot geometry is less controlled
- The baffles are important for lithium containment

# Divertor Heat Flux Dramatically Reduced

 Slot has difficulty getting below 5 MW/m<sup>2</sup> without reductions in upstream temperature

 Box can contain the lithium and reduce heat to the target further

#### Flow Reversal in Far SOL in Slot Geo.

 $-10^{22}$ 

1.0

- The far SOL lithium flow eventually becomes upstream-directed with enough lithium evaporation in the slot Downstream-directed Li Flow

#### Flow Never Reverses in Box Geo.

 In the box geometry the far SOL lithium flow is never reversed for any of the cases tested

# Thermal Gradient Location Leads to Important Differences

- Higher temperature within box leads to more radiation from the lithium due to higher  $\epsilon_{cool}$
- Box has more efficient lithium cooling, thus requiring a lower source so cooling requirements can be achieved without reversing flow in far SOL

#### Line Radiation Peaks Below X-Point

- Line radiation peaks at box entrance, succeeding in keeping radiation below X-point  $_{120}4 \times 10^{23}$  Li/s  $1 \times 10^{23}$  D<sub>2</sub>/s
