The physical characteristics of NTV investigated in tokamaks for rotation control and the evaluation of plasma response

Motivation

- □ Low magnitude ($\delta B/B_0 \sim O(10^{-3})$) 3D magnetic fields are used favorably used in tokamaks (e.g. ELM suppression, MHD mode control)
- 3D fields of this magnitude can produce neoclassical toroidal viscosity (NTV), which can:
 K.C. Shaing, et al., Nucl. Fusion 54 (2014) 033012
 - Alter plasma rotation

K.C. Shaing, et al., IAEA FEC 2014 Paper TH/P1-11

- Significantly reduce fusion gain, Q, by increased alpha particle transport $(\delta B/B_0 \sim O(10^{-4}))$
- □ Therefore, it is important to understand NTV in tokamaks, backed by accurate ($\sim O(1)$) quantitative modeling

Outline

- NTV physical characteristics
- NTV comparison of theory to experiment
- NTV experiments and assessment of plasma response
- □ Application of NTV to plasma rotation control for NSTX-U

Neoclassical Toroidal Viscosity (NTV) can be studied through the application of 3D fields in tokamaks

□ Theory: NTV strength varies with plasma collisionality ν , δB^2 , rotation

NSTX 3D coils

NTV physical characteristics are generally favorable for rotation control

- Non-resonant NTV characteristics (e.g. in NSTX and KSTAR)
 - □ 3D field configurations with dominant toroidal mode number n > 1 can alter the plasma rotation profile, ω_{ϕ} , without mode locking
 - Experimentally, NTV torque is radially extended, with a relatively smooth profile
 - NTV changes continuously as the applied 3D field is increased
 - T_{NTV} is not simply an integrated torque applied at the plasma boundary, but a radial profile – e.g. ω_{ϕ} shear can be changed
- These aspects are generally favorable for rotation control; give potential mode control
- Questions remain
 - e.g. Is there hysteresis when ω_{ϕ} is altered by NTV?

🔘 NSTX-U

KSTAR experiments show essentially no hysteresis in steady-state ω_{ϕ} profile vs. applied 3D field strength

- Experiment run to produce various steady-state ω_{ϕ} with different 3D field evolution
- □ The steady-state rotation profile reached is generally independent of the starting point of ω_{ϕ}
 - depends just on the applied3D field current level
 - important for rotation control
- Absence of hysteresis further confirmed in very recent experiments with 6 steps in 3D field current

Neoclassical Toroidal Viscosity varies as δB^2 , and $T_i^{2.27}$ in KSTAR experiments, expected by theory

(D) NSTX-U

3D field perturbation experiments conducted to measure the T_{NTV} profile in NSTX

- High normalized beta plasma targets typically chosen
 Typically near or above n = 1 no-wall limit (for higher *T_i*)
- Apply or otherwise change 3D field on a timescale significantly faster than the momentum diffusion time, τ_m
 - □ Analysis before/after 3D field application isolates T_{NTV} in the momentum diffusion equation; $-dL/dt = T_{NTV}$
- □ dL/dt measured experimentally and compared to theoretically computed T_{NTV} on this timescale
 - □ *dL/dt* profile can change significantly on timescales > τ_m , (diffuses radially, broadens, leads to significant error compared to T_{NTV})
- □ Focus on non-resonant applied 3D field configurations
 - To avoid driving MHD modes
 - □ Resonant fields (e.g. n = 1) are more strongly screened by plasma

Theoretical NTV torque density profiles, T_{NTV} are computed for NSTX using theory applicable to all collisionality regimes

NTV analysis of NSTX – data interfaced to NTVTOK

(Y. Sun, Liang, Shaing, et al., NF 51 (2011) 053015)

- Use Shaing's "connected NTV model", covers all v, superbanana plateau regimes (K.C. Shaing, Sabbagh, Chu, NF 50 (2010) 025022)
- Full 3D coil specification and δB spectrum, ion and electron components computed, no aspect ratio assumptions

<u>3D field definition</u>

$$\delta B = \vec{b} \bullet \left(\vec{B} / B \right) + \left(\vec{\xi} \bullet \nabla B \right)$$

plasma displacement

General considerations

- In tokamaks, ξ not typically measured, can lead to large error
- "Fully-penetrated field constraint" used to define ξ $\left(\vec{B}_{2D} \bullet \nabla \vec{\xi} = \vec{b}\right)$
 - Singularities avoided by standard finite island width assumption
- □ For NSTX, $|\xi| \sim 0.3$ cm << $\varepsilon^{0.5}\rho_i$, therefore, ion banana widthaveraging is used for ion channel
 - Can explain why strong resonant peaks in NTV profile are not observed in experiment

Measured NTV torque density profiles quantitatively compare well to computed T_{NTV} using fully-penetrated 3D field

 $\Box T_{NTV}$ (theory) scaled to match *peak* value of measured *-dL/dt*

- □ Scale factor $((dL/dt)/T_{NTV}) = 1.7$ and 0.6 (for cases shown above) O(1) agreement
- O(1) agreement using "fully-penetrated 3D field" indicates that plasma response is <u>not</u> strongly amplified from this "vacuum field assumption" ($T_{NTV} \sim \delta B^2$)

WNSTX-U

Plasma response from fully-penetrated 3D field used in NTV experimental analysis matches M3D-C¹ single fluid model

 $\frac{Surface-averaged \ \delta B \ from \ fully \ penetrated}{model \ vs. \ M3D-C^1 \ single \ fluid \ model}$

- NTV experimental data is a strong quantitative constraint on plasma response of δB
 - $\hfill\square$ Because the measured NTV scales as $T_{NTV} \propto \delta B^2,$
- Level of agreement varies along the profile
 - Good agreement between NTVTOK / M3D-C¹ single fluid models in strong NTV region
 - M3D-C¹ core <δB> larger than NTVTOK
 - Core mode in M3D-C¹
 - □ M3D-C¹ edge $<\delta$ B> smaller
 - Experimental T_{NTV} too small in this region to constraint δB

Non-resonant NTV and NBI used as actuators in state-space rotation feedback controller designed for NSTX-U

□ Momentum force balance – ω_{ϕ} decomposed into Bessel function states

$$\sum_{i} n_{i} m_{i} \left\langle R^{2} \right\rangle \frac{\partial \omega}{\partial t} = \left(\frac{\partial V}{\partial \rho} \right)^{-1} \frac{\partial}{\partial \rho} \left[\frac{\partial V}{\partial \rho} \sum_{i} n_{i} m_{i} \chi_{\phi} \left\langle \left(R \nabla \rho \right)^{2} \right\rangle \frac{\partial \omega}{\partial \rho} \right] + T_{NBI} + T_{NTV}$$

NTV torque:

$$T_{NTV} \propto K \times f\left(n_{e,i}^{K1} T_{e,i}^{K2}\right) g\left(\delta B(\rho)\right) \left[I_{coil}^{2} \omega\right] \quad (\text{non-linear})$$

OD NSTX-U

When T_i is included in NTV rotation controller model, 3D field current and NBI power can compensate for T_i variations

(III) NSTX-U

Physical characteristics of NTV are investigated in tokamaks for rotation control and the evaluation of plasma response

- Experiments on NSTX and KSTAR show that non-resonant NTV torque T_{NTV} from applied 3D field is a radially extended, relatively smooth profile
- □ Analysis of KSTAR shows $T_{NTV} \propto (\delta B_{3D})^2$; $T_{NTV} \propto T_i^{2.27}$; no hysteresis on the rotation profile when altered by non-resonant NTV (key for control)
- 3D field perturbation experiments in NSTX using both n = 2 and n = 3 field configurations measure the T_{NTV} profile
- The measured T_{NTV} profile quantitatively compares well between experiment and Shaing's "connected NTV theory" K.C. Shaing, et al., NF 50 (2010) 025022)
- Non-resonant T_{NTV} profile in NSTX is quantitatively consistent with "fullypenetrated field" assumption of plasma response
- Surface-averaged 3D field profile from M3D-C¹ single fluid model consistent with field used for quantitative NTV agreement in experiment
- Rotation controller using NTV and NBI designed/tested for NSTX-U

Non-resonant NTV and NBI used as actuators in state-space rotation feedback controller designed for NSTX-U

□ Momentum force balance – ω_{ϕ} decomposed into Bessel function states

$$\sum_{i} n_{i} m_{i} \left\langle R^{2} \right\rangle \frac{\partial \omega}{\partial t} = \left(\frac{\partial V}{\partial \rho} \right)^{-1} \frac{\partial}{\partial \rho} \left[\frac{\partial V}{\partial \rho} \sum_{i} n_{i} m_{i} \chi_{\phi} \left\langle \left(R \nabla \rho \right)^{2} \right\rangle \frac{\partial \omega}{\partial \rho} \right] + T_{NBI} + T_{NTV}$$

NTV torque:

$$T_{NTV} \propto K \times f\left(n_{e,i}^{K1} T_{e,i}^{K2}\right) g\left(\delta B(\rho)\right) \left[I_{coil}^{2} \omega\right] \quad (\text{non-linear})$$

OD NSTX-U

When T_i is included in NTV rotation controller model, 3D field current and NBI power can compensate for T_i variations

Measured NTV torque density profiles quantitatively compare well to computed T_{NTV} using fully-penetrated 3D field

- \Box T_{NTV} (theory) scaled to match *peak* value of measured *-dL/dt*
 - □ Scale factor $((dL/dt)/T_{NTV}) = 1.7$ and 0.6 (for cases shown above) O(1) agreement
 - O(1) agreement using "fully-penetrated 3D field" indicates that plasma response is <u>not</u> strongly amplified from this "vaccum field assumption" ($T_{NTV} \sim \delta B^2$)

OD NSTX-U

Very recently, high beta plasmas transiently reached $\beta_N = 4$ in 2014 campaign

S.W. Yoon, et al., IAEA FEC 2014 paper OV/3-4 (Tues. AM)

- Values obtained using fully converged KSTAR EFIT reconstructions
- High values reached transiently at lowered B_t
 - □ B_T in range 0.9 1.2 T
 - β_N up to 4 with l_i ~ 0.8 for duration longer than τ_E
 ~60 ms in these discharges
- Adding newly available 3rd neutral beam source may further increase the operating performance in the ongoing device campaign

OD NSTX-U

Non-resonant Neoclassical Toroidal Viscosity (NTV) physics will be used for the first time in rotation feedback control

• Momentum force balance – ω_{ϕ} decomposed into Bessel function states $\sum_{i} n_{i} m_{i} \left\langle R^{2} \right\rangle \frac{\partial \omega}{\partial t} = \left(\frac{\partial V}{\partial \rho} \right)^{-1} \frac{\partial}{\partial \rho} \left[\frac{\partial V}{\partial \rho} \sum_{i} n_{i} m_{i} \chi_{\phi} \left\langle \left(R \nabla \rho \right)^{2} \right\rangle \frac{\partial \omega}{\partial \rho} \right] + T_{NBI} + T_{NTV}$

□ NTV torque:

$$T_{NTV} \propto K \times f\left(n_{e,i}^{K1} T_{e,i}^{K2}\right) g\left(\delta B(\rho)\right) \left[I_{coil}^{2} \omega\right] \quad (\text{non-linear})$$

INSTX-U

Plasma rotation control has been demonstrated for the first time with TRANSP using NBI and NTV actuators

(III) NSTX-U

25th IAEA Fusion Energy Conference: Characteristics of NTV for Rotation Control / Plasma Response (S.A. Sabbagh, et al.)

20 October 14th, 2014

EX/1-4: Physical Characteristics of Neoclassical Toroidal Viscosity in Tokamaks for Rotation Control and the Evaluation of Plasma Response

Highlights

Experimental NTV characteristics

- NTV experiments on NSTX and KSTAR
- NTV torque T_{NTV} from applied 3D field is a radially extended, relatively smooth profile
- Perturbation experiments measure T_{NTV} profile

Aspects of NTV for rotation control

- □ Varies as δB^2 ; $T_{NTV} \propto T_i^{5/2}$ in primary collisionality regime for large tokamaks
- No hysteresis on the rotation profile when altered by non-resonant NTV is key for control
- Rotation controller using NTV and NBI tested for NSTX-U; model-based design saves power

□ NTV analysis to assess plasma response

- Non-resonant NTV quantitatively consistent with fully-penetrated field assumption
- Surface-averaged 3D field profile from M3D-C¹ single fluid model consistent with field used for quantitative NTV agreement in experiment

Perturbation experiments measure NTV torque profile and compare to theory

Rotation controller using NTV and NBI
