## **Excitation of zonal flows and their impact on dynamics of edge pedestal collapse**

*Friday, 21 October 2016 08:30 (4 hours)*

We study the role of zonal flows in edge pedestal collapse using a reduced magnetohydrodynamic (MHD) model. A dramatic change of dynamics happens when ideal ballooning modes are stabilized. A detailed analysis shows that a zonal flow driven instability is developed due to a strong excitation of zonal vorticity, resulting in secondary crashes. The presence of subsidiary bursts after a main crash increases the effective crash time and energy loss. These simulation results resemble the behavior of compound edge localized modes (ELMs). Thus, our results indicate that a complete understanding of ELM crash dynamics requires the self-consistent inclusion of nonlinear zonal flows-MHD interaction and transport physics.

### **Paper Number**

TH/8-3

### **Country or International Organization**

Republic of Korea

**Primary author:** Dr JHANG, Hogun (National Fusion Research Institute)

**Presenter:** Dr JHANG, Hogun (National Fusion Research Institute)

**Session Classification:** Poster EX/9, EX/10, TH/7, TH/8, IFE/1, MPT/1, FNS/1

**Track Classification:** THS - Magnetic Confinement Theory and Modelling: Stability
