Excitation of zonal flows and their impact on dynamics of edge pedestal collapse

Friday, 21 October 2016 18:20 (20 minutes)

We study the role of zonal flows in edge pedestal collapse using a reduced magnetohydrodynamic (MHD) model. A dramatic change of dynamics happens when ideal ballooning modes are stabilized. A detailed analysis shows that a zonal flow driven instability is developed due to a strong excitation of zonal vorticity, resulting in secondary crashes.

The presence of subsidiary bursts after a main crash increases the effective crash time and energy loss. These simulation results resemble the behavior of compound edge localized modes (ELMs). Thus, our results indicate that a complete understanding of ELM crash dynamics requires the self-consistent inclusion of nonlinear zonal flows-MHD interaction and transport physics.

Paper Number

TH/8-3

Country or International Organization

Republic of Korea

Primary author: Dr JHANG, Hogun (National Fusion Research Institute)

Co-authors: Dr KAANG, Helen H (NFRI); Prof. SINGH, Raghvendra (ITER-Cadarache / IPR-India); Dr KIM, S S (NFRI); Prof. HAHM, Taik Soo (Seoul National University); Dr RHEE, Tongnyeol (NFRI, Daejeon, South Korea)

Presenter: Dr JHANG, Hogun (National Fusion Research Institute)

Session Classification: ELMs Suppression & Dynamics

Track Classification: THS - Magnetic Confinement Theory and Modelling: Stability
