Cognitive Radioecology

Natalia SEMIOSHKINA (WIn Germany), Gabriele VOIGT (WIn IAEA)

ABSTRACT

Radioecology is a branch of ecology, which studies how radioactive substances interact with nature; how different mechanisms affect the substances’ migration and uptake in food chains and ecosystems [Wikipedia]. Investigations in radioecology might include aspects of field sampling, designed field and laboratory experiments and the development of predictive simulation models. This science combines techniques from some of the more basic, traditional fields, such as physics, chemistry, mathematics, biology, and ecology, with applied concepts in radiation protection. Radioecological studies form the basis for estimating doses and assessing the consequences of radioactive pollution for human health and the environment.

Significant economic and social disruptions arise after radioactive contamination of land as a result of releases of radioactivity into the environment be it from accidents, routine and war operations or during decommissioning and waste management of nuclear facilities. Measures carried out to reduce and minimise radiation doses to the public can give rise to even more concerns as often they are not understood and the stakeholders are often not involved into the decision making process. Countermeasures are needed to reduce population exposure, at the same time minimising economic and social costs. The effectiveness of countermeasures is not only highly dependent on factors which are connected to environmental transfer, but also to special behaviour and consumption behaviours in varying food production systems. It is clearly desirable that countermeasures are implemented in the most effective way, targeting expensive resources to areas and/or products for which they are most required at the same time minimizing their social and economic and ecological impact.

A central aspect of radioecology is the identification of vulnerable areas which, by virtue of the processes governing the transfer of radioisotopes through food chains, deliver high individual, or collective doses to man. Social factors (e.g. dietary preferences) and agricultural production techniques also contribute to vulnerability. Modern geographical information systems combing all such information reliably based on experimental and measurement studies and scientific knowledge support the identification of such areas allowing to redirect resources and inform authorities and the public about the actual and future developments.

NUCLEAR ACCIDENTS AND TESTS

ENVIRONMENTAL TRANSPORT

TERRESTRIAL • ATMOSPHERIC • AQUATIC

ATMOSPHERIC PATHWAY

Direct radiation from radionuclides in the plume or deposited on the ground: external exposure
Inhalation of radionuclides in the air or ingestion of food or other materials (soil) that have been contaminated by radioactive materials: internal exposure

AQUATIC PATHWAY

Drinking water
Consumption of vegetables, meat, milk and soil affected by the use of contaminated irrigation water
Consumption of fish, shellfish and seaweeds
External exposure though swimming and boating
Direct exposure from contaminated shore sediment

TERRESTRIAL PATHWAY

Direct exposure from radionuclides in deposited on the ground: external exposure
Ingestion of food or other materials (soil) that have been contaminated by radioactive materials: internal exposure

RADIOECOLOGICAL ACTIVITIES

SAMPLING and in-SITU measurements
Laboratory experiments on radionuclide migration in soil, transfer to plant, transfer to animals

CALCULATION AND SIMULATION

Calculation of the dose to man, based on measurements. Modelling of the radionuclide transfer and their behaviour in environment

ENVIRONMENTAL DECISION SUPPORT SYSTEM

Because of the multiple factors affecting the efficiency and suitability of each countermeasure, generalised recommendation - which do not account for diversity - often, result in inadequate decisions when applied at a local scale. These considerations have led to a need for a development of practical environmental decision support systems (EDSS) which take into account the temporal and spatial variation in the above factors and are capable of providing advice on countermeasure strategies at different levels of the decision making process. Due to developments in information technology (IT) and tools such as GIS and Multi-Criteria Decision Support (MCDS) systems, it has become possible to integrate spatial, temporal and additional criteria into one decision making system.
